MARCO MAGGESI, Univ. Florence, Italy

We propose an initial-algebra semantics framework for syntax with variable binding inspired by De Bruijn representation with nameless dummies. Following Fiore, Plotkin, and Turi, our framework is substitutional, in the sense that models all come equipped with a substitution operation. It is however more elementary than their presheaf-based framework. Furthermore, we establish a strong link with Fiore, Plotkin, and Turi's. Finally, we extend the framework and the notion of signature to accommodate simple types and equations between terms.

Additional Key Words and Phrases: variable binding; category theory

#### 1 INTRODUCTION

There is a standard notion of signature for syntax with variable binding called *binding signature*. Such a signature consists of a set of operation symbols, together with, for each of them, a *binding arity*, namely a list of natural numbers, specifying the number of bound variables in each argument.

Among the many possible representations of the syntax specified by a binding signature *S*, we focus on De Bruijn's encoding with nameless dummies [De Bruijn 1972]. Let us stress some of its features.

**Terms** The set  $DB_S$  of terms is the least fixed point of a suitable endofunctor on sets, of the shape  $X \mapsto \mathbb{N} + \Sigma_S(X)$ , where  $\mathbb{N}$  accounts for variables and  $\Sigma_S(X)$  for operations.

In particular,  $DB_S$  is equipped with a **variables** map  $v \colon \mathbb{N} \to DB_S$  and, for each operation o from S, a map  $o_{DB_S} \colon DB_S^n \to DB_S$ , where n denotes the length of the binding arity of o.

**Substitution**  $DB_S$  is equipped with a **(parallel) substitution** map  $-[-]: DB_S \times DB_S^{\mathbb{N}} \to DB_S$ , of which we list some properties:

**Associativity** for all  $t \in DB_S$ ,  $f, g: \mathbb{N} \to DB_S$ ,  $t[f][g] = t[x \mapsto f(x)[g]]$ ,

**Right unitality** for all  $t \in DB_S$ , t[v] = t,

**Left unitality** for all  $n \in \mathbb{N}$  and  $f : \mathbb{N} \to DB_S$ , v(n)[f] = f(n), and

**Compatibility with operations** for each operation o with binding arity  $(n_1, \ldots, n_p), e_1, \ldots, e_p \in X$ , and  $f : \mathbb{N} \to X$ ,

$$o_{\mathrm{DB}_{S}}(e_{1},\ldots,e_{p})[f] = o_{\mathrm{DB}_{S}}(e_{1}[\uparrow]^{n_{1}}f],\ldots,e_{p}[\uparrow]^{n_{p}}f]), \tag{1}$$

where  $\uparrow$  is a unary operation defined on  $DB_S^{\mathbb{N}}$  by

$$\begin{array}{rcl} (\ \!\!\!\! \uparrow \sigma)(0) & = & v(0) \\ (\ \!\!\!\! \uparrow \sigma)(n+1) & = & \sigma(n)[n \mapsto v(n+1)]. \end{array}$$

In the present work, we integrate these features in a simple theory for syntax, essentially consisting of the following definitions and theorems, where *S* denotes any binding signature.

Authors' addresses: André Hirschowitz, Univ. Côte d'Azur, CNRS, LJAD, 06103, Nice, France; Tom Hirschowitz, Univ. Grenoble Alpes, Univ. Savoie Mont Blanc, CNRS, LAMA, 73000, Chambéry, France; Ambroise Lafont, UNSW, Sydney, Australia; Marco Maggesi, Univ. Florence, Florence, Italy.

**De Bruijn monad** A De Bruijn monad is a set *X*, equipped with

- a **substitution** map  $-[-]: X \times X^{\mathbb{N}} \to X$ , which takes an element  $x \in X$  and an assignment  $f: \mathbb{N} \to X$ , and returns an element x[f], and
- a **variables** map  $v \colon \mathbb{N} \to X$ , satisfying (abstract versions of) associativity, left and right unitality, and compatibility with operations. Of course, **DB**<sub>S</sub> forms a De Bruijn monad.

**De Bruijn** *S*-algebra A De Bruijn *S*-algebra is a De Bruijn monad (X, -[-], v) equipped with maps  $o_X : X^p \to X$  for each operation o in S with binding arity  $(n_1, \ldots, n_p)$ , satisfying Equation (1) (with  $o_{DB_S}$  replaced with  $o_X$ ).

# The term De Bruijn S-algebra

- (1) Substitution  $-[-]: \mathbf{DB}_S \times \mathbf{DB}_S^{\mathbb{N}} \to \mathbf{DB}_S$  is the unique map such that
  - (i) for all  $n \in \mathbb{N}$  and  $f : \mathbb{N} \to \mathbf{DB}_S$ , v(n)[f] = f(n), and
  - (ii) for each operation o in S with binding arity  $a = (n_1, \ldots, n_p)$ ,  $o_{DB_S} : DB_S^p \to DB_S$  satisfies the a-binding condition (1).
- (2) This map upgrades  $DB_S$  into a De Bruijn S-algebra.

**Category of De Bruijn** *S***-algebras** De Bruijn *S*-algebras are the objects of a category *S* - **DBAlg**, whose morphisms, as expected, are all maps between underlying sets that commute with variables, substitution, and operations.

# **Initial Semantics** Finally, **DB**<sub>S</sub> is initial in S - **DBAlg**.

We thus propose a theory for syntax with substitution, which is an alternative to the mainstream initial-algebra semantics of [Fiore et al. 1999]. We have experienced its simplicity by formalising it not only in Coq, but also in HOL light, which does not support dependent types.

Our theory is similar to the mainstream theory [Fiore et al. 1999], in the following aspects:

- Our and their basic definitions of syntax can be recast using relative monads: De Bruijn monads are monads relative to the full and faithful embedding  $\{\mathbb{N}\} \to \mathbf{Set}$ , while their substitution monoids are monads relative to the full and faithful embedding into  $\mathbf{Set}$  of the category of finite ordinals and arbitrary maps between them.
- We find (Theorem 5.22) that both approaches, in their own ways, include exotic models, and that when freed from them, our category of De Bruijn *S*-algebras and their category of *S*-models become equivalent. In this sense, both semantics differ only marginally.
- In §6, we show how De Bruijn *S*-algebras can be defined by resorting to (a slight generalisation [Borthelle et al. 2020] of) *pointed strong endofunctors*, in the spirit of [Fiore et al. 1999].
- Their theory covers simple types and equations; we also provide such extensions of our theory in §8 and §9.

# Related work

This paper is mainly about substitutional initial-algebra semantics. All frameworks we know of for substitutional initial-algebra semantics, e.g., Arkor and McDermott [2021]; Hirschowitz and Maggesi [2007, 2010], are variants of Fiore et al. [1999], with which we establish a strong link in §5.

Beyond this, the most closely related work is the **nominal sets** approach [Gabbay and Pitts 1999], which comes equipped with induction and recursion principles [Pitts 2006]. Such principles may be used to define capture-avoiding substitution.

Also related are the diverse proof assistant libraries or extensions for variable binding [Allais et al. 2018; Schäfer et al. 2015b; Stark et al. 2019; Urban 2008], which are more mature than our formalisation. A distinctive feature of our approach is its emphasis on **substitutional** initial algebra semantics, in the sense of defining a category of models (featuring substitution) for each signature,

and characterising syntax as the initial object therein. This readily enables, e.g., reasoning about denotational semantics. But there are further differences. E.g., compared to Allais et al. [2018], an important difference is that we avoid indexing over free variables. A symptom of this is that their approach would be hard, if not impossible, to implement in a weak logic like HOL. The approach of Schäfer et al. [2015b]; Stark et al. [2019] does avoid indexing, but differs from ours in that it is external to the proof assistant's logic.

#### General notation

We denote by  $A^* = \sum_{n \in \mathbb{N}} A^n$  the set of finite sequences of elements of A, for any set A. In any category C, we tend to write [C, D] for the hom-set C(C, D) between any two objects C and D. Finally, let F - alg denote the usual category of F-algebras and morphisms between them.

# 2 DE BRUIJN MONADS

In this section, we start by introducing De Bruijn monads. Then, we define derivation of assignments, the binding conditions, and the models of a binding signature *S* in De Bruijn monads, De Bruijn *S*-algebras. Finally, we construct the term De Bruijn *S*-algebra.

#### 2.1 Elementary definition of De Bruijn monads

We start by fixing some terminology and notation, and then give the definition.

*Definition 2.1.* Given a set X, an X-assignment is a map  $\mathbb{N} \to X$ . We sometimes merely use "assignment" when X is clear from context.

**Notation 1.** Consider any map  $s: X \times Y^{\mathbb{N}} \to Z$ .

- For all  $x \in X$  and  $g: \mathbb{N} \to Y$ , we write  $x[g]_s$  for s(x,g), or even x[g] when s is clear from context.
- Furthermore, s gives rise to the map

$$\begin{array}{ccc} X^{\mathbb{N}} \times Y^{\mathbb{N}} & \to & Z^{\mathbb{N}} \\ (f,g) & \mapsto & n \mapsto s(f(n),g). \end{array}$$

We use similar notation for this map, i.e.,  $f[g](n) := f(n)[g]_s$ .

Definition 2.2. A **De Bruijn monad** is a set X, equipped with

- a **substitution** map  $s: X \times X^{\mathbb{N}} \to X$ , which takes an element  $x \in X$  and an assignment  $f: \mathbb{N} \to X$ , and returns an element x[f], and
- a variables map  $v: \mathbb{N} \to X$ ,

such that for all  $x \in X$ , and  $f, g: \mathbb{N} \to X$ , we have

$$x[f][g] = x[f[g]] \qquad v(n)[f] = f(n) \qquad x[v] = x.$$

*Example 2.3.* The set  $\mathbb N$  itself is clearly a De Bruijn monad, with variables given by the identity and substitution  $\mathbb N \times \mathbb N^\mathbb N \to \mathbb N$  given by evaluation. This is in fact the initial De Bruijn monad, as should be clear from the development below.

*Example 2.4.* The set  $\Lambda := \mu X.\mathbb{N} + X + X^2$  of  $\lambda$ -terms forms a De Bruijn monad. The variables map  $\mathbb{N} \to \Lambda$  is the obvious one, while the substitution map  $\Lambda \times \Lambda^{\mathbb{N}} \to \Lambda$  is less obvious but standard. In Example 2.16, as an application of Theorem 3.6, we will characterise this De Bruijn monad by a universal property.

# 2.2 Derivation of assignments

Given a De Bruijn monad M, we define an operation called **derivation** on its set of assignments  $\mathbb{N} \to M$ . It is convenient to stress that only part of the structure of De Bruijn monad is needed for this definition.

*Definition 2.5.* Consider any set M, together with a **lift** map  $\ell : M \to M$ , and a **first variable**  $z \in M$ . For any  $\sigma : \mathbb{N} \to M$ , we define the assignment  $\sigma' := \delta_{\ell,z}\sigma : \mathbb{N} \to M$  by

$$\sigma'(0) = z$$
  
$$\sigma'(n+1) = \ell(\sigma(n)).$$

In particular, for any set M equipped with maps  $s: M \times M^{\mathbb{N}} \to M$  and  $v: \mathbb{N} \to M$ , we take by default z = v(0) and  $\ell(x) = x[\uparrow]_s$ , where  $\uparrow: \mathbb{N} \to X$  maps any n to v(n+1).

Of course we may iterate derivation:

Definition 2.6. Let 
$$A^{(0)} = A$$
, and  $A^{(n+1)} = (A^{(n)})'$ .

#### 2.3 Binding arities and binding conditions

Our treatment of binding arities reflects the separation between the first-order part of the arity, namely its length, which concerns the syntax, and the binding information, namely the binding numbers, which concerns the compatibility with substitution.

Definition 2.7.

- A **first-order arity** is a natural number.
- A binding arity is a sequence  $(n_1, \ldots, n_p)$  of natural numbers, i.e., an element of  $\mathbb{N}^*$ .
- The first-order arity |a| associated with a binding arity  $a = (n_1, \dots, n_p)$  is its length p.

Let us now axiomatise what we call an operation of a given binding arity.

Definition 2.8. Let  $a=(n_1,\ldots,n_p)$  be any binding arity, M be any set,  $s: M\times M^{\mathbb{N}}\to M$ , and  $v:\mathbb{N}\to M$ . An operation **of binding arity** a is a map  $o:M^p\to M$  satisfying the following a-binding condition w.r.t. (s,v):

$$\forall \sigma \colon \mathbb{N} \to M, x_1, \dots, x_p \in M, \quad o(x_1, \dots, x_p)[\sigma] = o(x_1[\sigma^{(n_1)}], \dots, x_p[\sigma^{(n_p)}]). \tag{2}$$

**Remark 1.** Let us emphasise the dependency of this definition on v and s – which is hidden in the notations for substitution and derivation.

Now that we have a definition of an operation of a given binding arity, let us develop the standard approach to initial semantics.

#### 2.4 Binding signatures and algebras

In this section, we recall the standard notions of first-order (resp. binding) signatures, and adapt the definition of algebras to our De Bruijn context. Let us first briefly recall the former.

*Definition 2.9.* A **first-order signature** consists of a set O of **operations**, equipped with an **arity** map  $ar: O \to \mathbb{N}$ .

*Definition 2.10.* For any first-order signature S := (O, ar), an S-algebra is a set X, together with, for each operation  $o \in O$ , a map  $o_X : X^{ar(o)} \to X$ .

Let us now generalise this to binding signatures.

Definition 2.11.

- A binding signature consists of a set O of operations, equipped with an arity map ar: O →
  N\*. Intuitively, the arity of an operation specifies the number of bound variables in each
  argument.
- The first-order signature |S| associated with a binding signature S := (O, ar) is |S| := (O, |ar|), where  $|ar| : O \to \mathbb{N}$  maps any  $o \in O$  to |ar(o)|.

Example 2.12. The binding signature for  $\lambda$ -calculus has two operations lam and app, of respective arities (1) and (0,0). The associated first-order signature has two operations lam and app, of respective arities 1 and 2.

Let us now present the notion of De Bruijn *S*-algebra:

*Definition 2.13.* For any binding signature S := (O, ar), a **De Bruijn** S-algebra consists of a De Bruijn monad (X, s, v), together with, for all  $o \in O$ , an operation  $o_X$  of binding arity ar(o).

In order to state our characterisation of the term model, we associate to any binding signature an endofunctor on sets, as follows.

Definition 2.14. The endofunctor  $\Sigma_S$  associated to a binding signature (O, ar) is defined by  $\Sigma_S(X) = \sum_{o \in O} X^{|ar(o)|}$ .

**Remark 2.** The induced endofunctor just depends on the underlying first-order signature.

**Remark 3.** As is well known, for any binding signature, the initial  $(\mathbb{N} + \Sigma_S)$ -algebra has as carrier the least fixed point  $\mu A.\mathbb{N} + \Sigma_S(A)$ .

The following theorem defines the term model of a binding signature.

Theorem 2.15. Consider any binding signature S = (O, ar), and let  $DB_S$  denote the initial  $(\mathbb{N} + \Sigma_S)$ -algebra, with structure maps  $v \colon \mathbb{N} \to DB_S$  and  $a \colon \Sigma_S(DB_S) \to DB_S$ . Then,

- (i) There exists a unique map  $s: DB_S \times DB_S^{\mathbb{N}} \to DB_S$  such that
  - for all  $n \in \mathbb{N}$  and  $f : \mathbb{N} \to \mathbf{DB}_S$ , s(v(n), f) = f(n), and
  - for all  $o \in O$ , the map  $o_{DB_S}$  satisfies the ar(o)-binding condition w.r.t. (s, v).
- (ii) This map turns  $(DB_S, v, s, a)$  into a De Bruijn S-algebra.

Proof. We have proved the result in both HOL Light [Maggesi 2021] and Coq [Lafont 2021]. □

Remark 4. Point (i) is an abstract form of a recursive definition of substitution in the term model.

**Remark 5.** The theorem allows us to construct the term model of a signature in two steps: first the underlying set, constructed as the inductive datatype  $\mu Z.\mathbb{N} + \Sigma_S(Z)$ , and then substitution, defined by the binding conditions viewed as recursive equations.

*Example 2.16.* For the binding signature of  $\lambda$ -calculus (Example 2.12), the carrier of the initial model is  $\mu Z.\mathbb{N} + Z + Z^2$ .

# 3 INITIAL-ALGEBRA SEMANTICS OF BINDING SIGNATURES IN DE BRUIJN MONADS

In this section, for any binding signature *S*, we organise De Bruijn *S*-algebras into a category, *S* - **DBAlg**, and prove that the term De Bruijn *S*-algebra is initial therein.

#### 3.1 A category of De Bruijn monads

Let us start by organising general De Bruijn monads into a category:

Definition 3.1. A morphism  $(X, s, v) \to (Y, t, w)$  between De Bruijn monads is a set-map  $f: X \to Y$  commuting with substitution and variables, in the sense that for all  $x \in X$  and  $g: \mathbb{N} \to X$  we have  $f(x[g]) = f(x)[f \circ g]$  and  $f \circ v = w$ .

**Remark 6.** More explicitly, the first axiom says:  $f(s(x, g)) = t(f(x), f \circ g)$ .

**Notation 2.** De Bruijn monads and morphisms between them form a category, which we denote by **DBMnd**.

# 3.2 De Bruijn monads as relative monads and as monoids

In this subsection, we briefly mention a categorical point of view on the category of De Bruijn monads for the categorically-minded reader, in terms of **relative** monads [Altenkirch et al. 2015].

Proposition 3.2. The category **DBMnd** is canonically isomorphic to the category of monads relative to the functor  $1 \rightarrow \mathbf{Set}$  picking  $\mathbb{N}$ .

**Remark 7.** Canonicity here means that the isomorphism lies over the canonical isomorphism  $[1, Set] \cong Set$ .

According to the theory of [Altenkirch et al. 2015], this yields:

COROLLARY 3.3. The tensor product  $X \otimes Y := X \times Y^{\mathbb{N}}$  induces a skew monoidal [Szlachányi 2012] structure on Set, and DBMnd is precisely the category of monoids therein.

PROOF. To see this, let us observe that, by viewing any set X, in particular  $\mathbb{N}$ , as a functor  $1 \to \mathbf{Set}$ , one may compute the left Kan extension of X along  $\mathbb{N}$ , which is a functor  $\mathrm{Lan}_{\mathbb{N}}(X) \colon \mathbf{Set} \to \mathbf{Set}$ . By the standard formula for left Kan extensions [Mac Lane 1998], we have  $\mathrm{Lan}_{\mathbb{N}}(X)(Y) \cong X \times Y^{\mathbb{N}} = X \otimes Y$ .

# 3.3 Categories of De Bruijn algebras

In this section, for any binding signature *S*, we organise De Bruijn *S*-algebras into a category *S*-**DBAlg**.

Let us start by recalling the category of *S*-algebras for a first-order *S*:

Definition 3.4. For any first-order signature S, a morphism  $X \to Y$  of S-algebras is a map between underlying sets commuting with operations, in the sense that for each  $o \in O$ , letting p := ar(o), we have  $f(o_X(x_1, \ldots, x_p)) = o_Y(f(x_1), \ldots, f(x_p))$ .

We denote by *S* - alg the category of *S*-algebras and morphisms between them.

We now exploit this to define De Bruijn *S*-algebras:

Definition 3.5. For any binding signature S, a morphism of De Bruijn S-algebras is a map  $f: X \to Y$  between underlying sets, which is a morphism both of De Bruijn monads and of |S|-algebras. We denote by S-DBAlg the category of De Bruijn S-algebras and morphisms between them.

THEOREM 3.6. Consider any binding signature S = (O, ar), and let  $DB_S$  denote the initial  $(\mathbb{N} + \Sigma_S)$ -algebra. Then, the De Bruijn S-algebra structure of Theorem 2.15 on  $DB_S$  makes it initial in S - DBAlg.

Proof. Again, see §4. □

#### 4 MECHANISED PROOFS

Our theoretical framework is meant to help specify and reason mechanically about binding syntax using De Bruijn representation. To give practical examples, we describe in this section two implementations, in Coq and HOL Light, that cover several crucial parts of the theory of this paper, and, in particular Theorems 2.15 and 3.6. The full source code is available on github [Lafont 2021; Maggesi 2021].

# 4.1 HOL Light proof

Let us start by discussing the HOL Light formalization. One key fact is that, despite being much weaker than ZFC set theory or the Calculus of Inductive Constructions, HOL is expressive enough to program the De Bruijn encoding and to reason about it. For instance, other representations, such as those based on monads over sets [Hirschowitz and Maggesi 2010] (possibly via the nested datatype technique [Bird and Paterson 1999; Hirschowitz and Maggesi 2012]) are not directly implementable in HOL.

The reader does not need to be familiar with higher-order logic (HOL) to follow the essential ideas of this section. HOL is based on simply-typed  $\lambda$ -calculus. Following a standard denotational semantics in Zermelo-Fraenkel set theory, types in HOL can be thought of as non-empty sets.

Our HOL Light implementation is divided into two main parts. The first part treats the specific case of  $\lambda$ -calculus and can be useful to illustrate the essential ideas of this paper in a simple –yet paradigmatic– setting. In the following, identifiers in teletype font in parenthesis indicate names of the associated theorems in the code. HOL terms and formulas are enclosed in backquotes as in  $^2 + 2^2$ , types are prefixed by a colon as in  $^2 + 2^2$ .

The type :dblambda of  $\lambda$ -calculus is simply defined as the following inductive type

```
let dblambda_INDUCT, dblambda_RECURSION = define_type
  "dblambda = REF num | APP dblambda dblambda | ABS dblambda";;
```

while the HOL Light definition of substitution fits into the following five lines of code.

```
|- (!f i. SUBST f (REF i) = f i) /\
  (!f x y. SUBST f (APP x y) = APP (SUBST f x) (SUBST f y)) /\
  (!f x. SUBST f (ABS x) = ABS (SUBST (DERIV f) x)) /\
  (!f. DERIV f 0 = REF 0) /\
  (!f i. DERIV f (SUC i) = SUBST (REF o SUC) (f i))
```

The names `SUC` and `o` respectively denote successor and function composition. The symbols `/\` and `!` are HOL notations for conjunction and universal quantification. We recognise:

- in the first line, the variables map,
- in the next two lines, the binding conditions for application and abstraction, and
- in the final two lines, the recursive equations defining the derivative of an assignment.

This definition formalises the first point of Theorem 2.15 for the case of  $\lambda$ -calculus. More precisely, the first equation corresponds to the first item and the second and third equations are the two binding conditions for our signature and correspond to the second item.

The second point of the Theorem translates in the laws of associativity (SUBST\_SUBST) and two-sided unit (SUBST\_REF and the first equation of the above definition).

We also provide the classical definition of unary substitution (SUBST1, as found e.g., in Huet [1994]) and then show how the latter is an instance of the former (SUBST1\_EQ\_SUBST). As shown by other authors [Abadi et al. 1990; Schäfer et al. 2015a], reasoning on parallel substitution can be significantly easier. Here for instance, we prove the associativity of unary substitution in a few lines (SUBST1\_SUBST1) by reducing to parallel substitution. However, proving the same result

directly for unary substitution is less intuitive: the mere statement of the property to be proved by induction is tricky to devise.

Next, we introduce the category of De Bruijn monads (MONAD, MONAD\_MOR) and their associated modules (MODULE\_MOR). Our Definition 2.2 presents De Bruijn monads using a settheoretic style, hence as a triple constituted by a set, an associative substitution operator and a two-side identity. In HOL, this is translated into a type `:A` together with a substitution operation `op:(num->A)->A->A` and a unit `e:num->A`.¹ However, the unit is uniquely determined by the substitution operator and it is denoted `UNIT op` in our implementation. Moreover, the type `:A` is automatically inferred. Thus, we simply identify a De Bruijn monad by its substitution operator, that is, we write `op IN MONAD` to indicate that `op` is (the substitution operator of) a monad

```
|- !op. op IN MONAD <=>
     (!f g x:A. op g (op f x) = op (op g o f) x) /\
     (!f n. op f (UNIT op n) = f n) /\
     (!x. op (UNIT op) x = x)
```

The set of morphisms between two De Bruijn monads `op1` and `op2` is then defined as follows

Modules are implemented using a similar style. We implemented the constructions on modules needed for interpreting binding signatures: product (MPROD) and derivation (DMOP).

In this setup, we can state and prove Theorem 3.6 for the  $\lambda$ -calculus. The models of our syntax are De Bruin monads endowed with functions `app` and `abs` that are module morphisms (DBLAMBDA\_MODEL)

```
app IN MODULE_MOR op (MPROD op op, op)
lam IN MODULE_MOR op (DMOP op op, op)
```

Model morphisms (DBLAMBDA\_MODEL\_MOR) are morphisms of De Bruijn monads that commute with `app` and `abs`. We then have the universal property of  $\lambda$ -calculus by giving an initial model morphism (DBLAMBDAINIT, DBLAMBDAINIT\_IN\_DBLAMBDA\_MODEL\_MOR)

and by proving its uniqueness (DBLAMBDAINIT\_UNIQUE). This part closes with the analogous theorem for the initial semantics of  $\lambda$ -calculus modulo  $\beta\eta$  equivalence (EXP\_MONAD\_MOR\_LC\_EXPMAP, LC\_EXPMAP\_UNIQUE). The style is the one proposed in [Hirschowitz and Maggesi 2010] which uses exponential monads, that is, monads endowed with a module isomorphism (that gives *abstraction* of the monad) with their derivation.

The second part of the HOL Light code implements Theorems 2.15 and 3.6 for arbitrary signatures. The increased generality comes at a cost in this implementation: since HOL does not feature dependent types; it is impossible to implement the term algebra of a given binding signature as a mere type: one has to resort to a "well-formedness" predicate. From this perspective, it may be instructive to compare with our Coq implementation, which takes advantage of dependent types.

<sup>&</sup>lt;sup>1</sup>We warn the reader that in this code op is used for substitution operation and has not be confused with the operations of the syntax  $o \in O$  of the previous sections.

The above difficulty is solved in the standard way in HOL Light. First, we build a type rterm for *raw terms* over a "full" signature, i.e., one with countably many operations of each arity. We then introduce an inductive set (i.e., an inductive predicate) of well-formed terms (WELLFORMED\_RULES) that selects the terms respecting a given signature. Besides this technical difficulty, the formal development follows the same pattern as for  $\lambda$ -calculus.

The substitution operator is specified by two equations (TMSUBST\_CALUSES)

where `TMREF` denotes variables and `FN` denotes operations from the signature. The latter takes two arguments, the *name* of the construction `c` (a natural number) and a list of pairs `(k,x)' where `k` is a natural number denoting the number of bound variables and `x` is a  $\lambda$ -term.

We formulate the appropriate notion of category of models in this setting (MODEL, MODEL\_MOR) of which the above data constitutes an object (RTERM\_IN\_MODEL). Then we prove the universal property by giving the initial morphism (INITIAL\_MORPHISM\_IN\_MODEL\_MOR) and show its uniqueness (INITIAL\_MORPHISM\_UNIQUE).

We stress that our framework allows us to relate and reason on different syntaxes simultaneously and, for instance, prove theorems on a family of syntaxes. To give an example, we start by considering the trivial category structure on signatures given by inclusion. Then, we prove the functoriality (i.e., monotonicity) of our constructions (MODEL\_MONO, MODEL\_MOR\_MONO), and we show an easy but significant modularity result (INITIAL\_MORPHISM\_MODULARITY).

Finally, to tie the knot, we derive again the universal property for  $\lambda$ -calculus as an instance of this new, more general, framework (DBLAMBDA\_UNIVERSAL).

# 4.2 Coq proof

We now discuss the Coq formalisation. Our implementation addresses only the general case of arbitrary signatures since, as said before, we do not have significant advantages in treating a particular case separately thanks to the use of dependent types.

The reader who wants to skim through the main definitions and constructions of this implementation can look at file Summary.v that contains a sequence of checks of the *interface* based on the Coq mechanism of type inference and normalization.

The formalisation has an idiomatic style: the minute details of implementation pose no significant problem. Therefore, we just point the reader to the most relevant parts.

File syntaxdb.v starts with the notion of binding condition (binding\_condition) and the definition of the category of models associated to a binding signatures S (model, model\_mor).

Next, we introduce the algebra of terms Z, together with the substitution operator Z\_subst and verify its properties.

Then we define the initial morphism ini\_mor and prove its uniqueness. All this, again, constitutes a full formal counterpart of Theorem 3.6.

This part is free from axioms. In particular, we avoid the axiom of functional extensionality, stating that pointwise equal functions are equal. Instead, we require that substitution in a De Bruijn monad X is compatible with pointwise equality: if  $f, g : \mathbb{N} \to X$  are pointwise equal, then x[f] = x[g] for any  $x \in X$ .

The other main file is quotsyntax.v. There, the previous constructions are upgraded to the context of syntax with equation (equational\_theory). Here we use an axiomatic theory of quotients (developed in file Quot.v) to build the initial model ZE, and to define the initial morphism int\_morE.

In the same file, we also provide the instatiation on the equational signature  $LC\beta\eta_-$ sig of  $\lambda$ -calculus modulo  $\beta$  and  $\eta$  equations.

Overall, about one-third of the formalisation is devoted to the definitions and proofs up to Theorems 2.15 and 3.6. The rest focus on initiality for signatures with equations (Theorem 9.6), in the untyped setting.

#### 5 RELATION TO PRESHEAF-BASED MODELS

The classical initial-algebra semantics introduced in Fiore et al. [1999] associates in particular to each binding signature S a category, say  $\Phi_S$  - **Mon** of models, while we have proposed in §3 an alternative category of models S - **DBAlg**. In this section, we are interested in comparing both categories of models.

In fact, we find that both include exotic models, in the sense that we do not see any loss in ruling them out. And when we do so, we obtain equivalent categories.

# 5.1 Trimming down presheaf-based models

First of all, in this subsection, let us recall the mainstream approach we want to relate to, and exclude some exotic objects from it.

5.1.1 Presheaf-based models. We start by recalling the presheaf-based approach. The ambient category is the category of functors  $[\mathbb{F}, \mathbf{Set}]$ , where  $\mathbb{F}$  denotes the category of finite ordinals, and all maps between them.

*Definition 5.1.* Let [Set, Set]<sub>f</sub> denote the full subcategory of [Set, Set]<sub>f</sub> spanning **finitary** functors, i.e., those preserving directed colimits (= colimits of directed posets).

Proposition 5.2. The restriction functor [Set, Set]  $_f \to [\mathbb{F}, \operatorname{Set}]$  is an equivalence.

PROOF. By Adámek and Rosický [1994, Theorem 2.26(ii)] and Adámek and Rosický [1994, Remark 2.26(1)], with  $\mathcal{K} = \mathbf{Set}$ , observing that finitely presentable objects of sets are equivalent to  $\mathbb{F}$ , so we may take  $\mathscr{A} = \mathbb{F}$ .

*Definition 5.3.* Let  $(\otimes, I)$  denote the monoidal structure on  $[\mathbb{F}, \mathbf{Set}]$  inherited from the composition monoidal structure on  $[\mathbf{Set}, \mathbf{Set}]_f$  through the equivalence of Proposition 5.2.

By construction, monoids in  $[\mathbb{F}, Set]$  are thus equivalent to finitary monads on sets.

The idea is then to interpret binding signatures S as endofunctors  $\Phi_S$  on  $[\mathbb{F}, \mathbf{Set}]$ , and to define models as monoids equipped with  $\Phi_S$ -algebra structure and satisfying a suitable compatibility condition.

The definition of  $\Phi_S$  relies on a form of derivation:

Definition 5.4 (Endofunctor associated to a binding signature).

- Let the **derivative** X' of any functor  $X : \mathbb{F} \to \mathbf{Set}$  be defined by X'(n) = X(n+1).
- Furthermore, let  $X^{(0)} = X$ , and  $X^{(n+1)} = (X^{(n)})'$ .
- For any binding arity  $a = (n_1, ..., n_p)$ , let  $\Phi_a(X) = X^{(n_1)} \times ... \times X^{(n_p)}$ .
- For any binding signature S = (O, ar), let  $\Phi_S = \sum_{o \in O} \Phi_{ar(o)}$ .

PROPOSITION 5.5. Through the equivalence with finitary functors, derivation becomes F'(A) = F(A+1), for any finitary  $F : \mathbf{Set} \to \mathbf{Set}$  and  $A \in \mathbf{Set}$ .

*Example 5.6.* For the binding signature  $S_{\lambda}$  of Example 2.12 for  $\lambda$ -calculus we get  $\Phi_{S_{\lambda}}(X)(n) = X(n)^2 + X(n+1)$ .

Next, we want to express the relevant compatibility condition between algebra and monoid structure. For this, let us briefly recall the notion of pointed strength, see Fiore [2008]; Fiore et al. [1999] for details.

Definition 5.7. A **pointed strength** on an endofunctor  $F: \mathbb{C} \to \mathbb{C}$  on a monoidal category  $(\mathbb{C}, \otimes, I, \alpha, \lambda, \rho)$  is a family of morphisms  $st_{C,(D,v)}: F(C) \otimes D \to F(C \otimes D)$ , natural in  $C \in \mathbb{C}$  and  $(D,v:I\to D)\in I/\mathbb{C}$ , the coslice category below D, making the following diagrams commute,

$$F(A) \otimes I \xrightarrow{F(PA)} F(A \otimes I)$$

$$F(A) \otimes X \otimes Y \xrightarrow{st_{A,(X,v_X)} \otimes Y} F(A \otimes X) \otimes Y \xrightarrow{st_{A\otimes X,(Y,v_Y)}} F((A \otimes X) \otimes Y)$$

$$\downarrow F(A) \otimes (X \otimes Y) \xrightarrow{st_{A,(X,v_X)} \otimes Y} F(A \otimes X) \otimes Y \xrightarrow{st_{A\otimes X,(Y,v_Y)}} F(A \otimes X) \otimes Y)$$

$$\downarrow F(A) \otimes (X \otimes Y) \xrightarrow{st_{A,(X,v_X)} \otimes Y} F(A \otimes X) \otimes Y$$

where  $v_X: I \to X$  and  $v_Y: I \to Y$  are the given points, and  $v_{X \otimes Y}$  denotes the composite

$$I \xrightarrow{\rho_I} I \otimes I \xrightarrow{v_X \otimes v_Y} X \otimes Y.$$

The next step is to observe that binding signatures generate pointed strong endofunctors.

*Definition 5.8.* The derivation endofunctor  $X \mapsto X'$  on  $[\mathbb{F}, \mathbf{Set}]$  has a pointed strength, defined through the equivalence with finitary functors by

$$G(F(X) + 1) \xrightarrow{G(F(X) + v_1)} G(F(X) + F(1)) \xrightarrow{G[F(in_1), F(in_2)]} G(F(X + 1)).$$

Product, coproduct, and composition of endofunctors lift to pointed strong endofunctors, which yields:

Corollary 5.9 (Fiore [2008]; Fiore et al. [1999]). For all binding signatures S,  $\Phi_S$  is pointed strong.

We arrive at last at the definition of models.

*Definition 5.10.* For any pointed strong endofunctor F on C, an F-monoid is an object X equipped with F-algebra and monoid structure, say  $a: F(X) \to X$ ,  $s: X \otimes X \to X$ , and  $v: I \to X$ , such that the following pentagon commutes.

$$\begin{array}{c|c} F(X) \otimes X \xrightarrow{st_{X,(X,v)}} F(X \otimes X) \xrightarrow{F(s)} F(X) \\ a \otimes X \downarrow & \downarrow a \\ X \otimes X \xrightarrow{s} X \end{array}$$

A morphism of F-monoids is a morphism in C which is a morphism both of F-algebras and of monoids. We let F-Mon denote the category of F-monoids and morphisms between them.

*Example 5.11.* For the binding signature  $S_{\lambda}$  of Example 2.12, a  $\Phi_{S_{\lambda}}$ -monoid is an object X, equipped with maps  $X' \to X$  and  $X^2 \to X$ , and compatible monoid structure. Compatibility describes how substitution should be pushed down through abstractions and applications.

5.1.2 Well-behaved presheaves. The exoticness we want to rule out concerns only the underlying functor of a model, so we just have to define well-behaved functors in  $[\mathbb{F}, \mathbf{Set}]$ .

Well-behavedness for a functor  $T \colon \mathbb{F} \to \mathbf{Set}$  is about getting closed terms right. More precisely, for some finite sets m and n, an element of T(m+n) which both exists in T(m) and T(n) should also exist in  $T(\emptyset)$ , and uniquely so. This says exactly that T should preserve the pullback

$$0 \longrightarrow n \\
\downarrow \longrightarrow \downarrow \\
m \longrightarrow m+n.$$

Furthermore, the following two known results will help us show that all non-empty pullbacks are automatically preserved.

Proposition 5.12 (Trnková [1969, Proposition 2.1]). All endofunctors of sets preserve non-empty intersections.

Thus, by Proposition 5.2 all functors  $\mathbb{F} \to \mathbf{Set}$  preserve non-empty intersections, and we have:

COROLLARY 5.13. A functor  $\mathbb{F} \to \mathbf{Set}$  preserves (binary) intersections iff it preserves empty (binary) intersections.

Definition 5.14.

- A functor  $\mathbb{F} \to \mathbf{Set}$  is **well-behaved** iff it preserves binary intersections, or equivalently empty binary intersections. Let  $[\mathbb{F}, \mathbf{Set}]_{wb}$  denote the full subcategory spanned by well-behaved functors.
- For any binding signature S, an object of  $\Phi_S$  **Mon** is **well-behaved** iff the underlying functor is. Let  $\Phi_S$  **Mon**<sub>wb</sub> denote the full subcategory spanned by well-behaved objects.

*Example 5.15.* As an example of a non well-behaved finitary monad, consider the monad L of  $\lambda$ -calculus but edited so that  $L(\emptyset) = \emptyset$ .

The important result for comparing the presheaf-based approach with ours is the following.

Proposition 5.16. The subcategory  $\Phi_S$  - **Mon**<sub>wb</sub> includes the initial object.

PROOF. Roughly, closed terms are isomorphic to terms in two free variables that use neither the first, nor the second.

Let us conclude this subsection with the following observation, that for a wide class of signatures all models are in fact well behaved.

PROPOSITION 5.17. If the initial object  $DB_S$  of  $\Phi_S$  - Mon has at least one closed term (i.e.,  $DB_S(\emptyset) \neq \emptyset$ ), then  $\Phi_S$  - Mon<sub>wb</sub> =  $\Phi_S$  - Mon.

PROOF. If T is a  $\Phi_S$ -monoid, then by initiality there is a morphism  $\mathbf{DB}_S \to T$ , and in particular a map  $\mathbf{DB}_S(0) \to T(0)$ . Since  $\mathbf{DB}_S(0)$  is not empty by assumption, T(0) cannot be empty. The result then follows from [Adámek et al. 2012, Proposition VII.7]: a monad T on **Set** either preserves the initial object, or is well-behaved.

**Remark 8.** The signatures for which the initial model has at least one closed term are those specifying at least a constant or an operation binding (at least) one variable in each argument.

# 5.2 Trimming down De Bruijn monads

Let us now turn to well-behaved De Bruijn algebras. Here well-behavedness is about finitariness. However, it may not be immediately clear how to define finitariness of a De Bruijn monad.

Definition 5.18. A De Bruijn monad (X, s, v) is finitary iff each of its elements  $x \in X$  has a (finite) support  $N_x \in \mathbb{N}$ , in the sense that for all  $f : \mathbb{N} \to \mathbb{N}$  fixing the first  $N_x$  numbers, the corresponding renaming  $v \circ f$  fixes x.

PROPOSITION 5.19. Let  $x \in X$  be an element of a De Bruijn monad (X, s, v). The following are equivalent:

- (1) x has support N;
- (2) given assignments  $f_1, f_2 : \mathbb{N} \to X$  which coincide on the first N numbers,  $x[f_1] = x[f_2]$ .
- (3) for any assignment  $f : \mathbb{N} \to X$  fixing the first N variables (in the sense that f(n) = v(n) for any n < N), x[f] = x;

PROOF. (1)  $\Rightarrow$  (2) Suppose given two assignments  $f_1, f_2 : \mathbb{N} \to X$  such that  $f_1(n) = f_2(n)$  for any n < N. Consider a bijection  $s : \mathbb{N} \to \mathbb{N}$  If  $\mathbb{N}$ . For  $i \in \{1, 2\}$ , let  $h_i : \mathbb{N} \to \mathbb{N}$  be the function fixing the first N numbers and mapping  $n \ge N$  to  $s^{-1}(in_i(n))$ , where  $in_1, in_2 : \mathbb{N} \to \mathbb{N}$  If  $\mathbb{N}$  are the canonical injections. Let  $u : \mathbb{N} \to X$  mapping n < N to  $f_1(n) = f_2(n)$  and  $n \ge N$  to  $[f_1, f_2](s(n))$ , where  $[f_1, f_2] : \mathbb{N}$  If  $\mathbb{N} \to \mathbb{N}$  is the canonical morphism induced by  $f_1$  and  $f_2$ . Then,  $f_i = u \circ h_i$ , for  $i \in \{1, 2\}$ . Thus,  $x[f_i] = x[u \circ h_i] = x[v \circ h_i][u]$ . Now, since x has support x is the canonical morphism.

- (2)  $\Rightarrow$  (3) Suppose given an assignment  $f: \mathbb{N} \to X$  fixing the first N variables. Then, f coincides with v on the first N variables. Thus, x[f] = x[v] = x.
- (3) ⇒ (1) Let  $f : \mathbb{N} \to \mathbb{N}$  fixing the first N numbers. Then,  $v \circ f$ , as an assignment, also does. Thus,  $x[v \circ f] = x$ .

*Definition 5.20.* For any binding signature S, let S -  $\mathbf{DBAlg}_{wb}$  denote the full subcategory spanning De Bruijn S-algebras whose underlying De Bruijn monad is finitary.

Proposition 5.21. The subcategory S -  $DBAlg_{wb}$  includes the initial object.

# 5.3 Bridging the gap

We may at last state the relationship between initial-algebra semantics in presheaves and in De Bruijn monads:

Theorem 5.22. Consider any binding signature S. The subcategories  $\Phi_S$  -  $\mathbf{Mon}_{wb}$  and S -  $\mathbf{DBAlg}_{wb}$  are equivalent.

PROOF. See [Hirschowitz et al. 2021b, Appendix A].

**Remark 9.** The moral of this is that, if one removes exotic objects from both  $\Phi_S$  - Mon and S - DBAlg, then one obtains equivalent categories, which both retain the initial object. Thus, the two approaches to initial-algebra semantics of binding signatures differ only marginally.

#### **6 STRENGTH-BASED INTERPRETATION OF THE BINDING CONDITIONS**

In the previous section, we have compared the category S - **DBAlg** of models of a binding signature in De Bruijn monads with the standard category of S-monoids [Fiore et al. 1999].

In this section, we recast the development of §3 in an abstract framework for variable binding, also initiated by Fiore et al. [1999]. This framework was originally based on **pointed strong** endofunctors on **monoidal** categories [Fiore 2008; Fiore et al. 1999]. However, we have seen in §3.2

that  $\mathbb{N}$  and the tensor product equip **Set** with skew monoidal structure, so we need to use the corresponding generalisation of pointed strengths proposed by Borthelle et al. [2020].

In summary, we show that any binding signature S = (O, ar) gives rise to a so-called **structurally strong** endofunctor  $\Sigma_S$  on **Set**, equipped with the skew monoidal structure of Corollary §3.3. The corresponding category of models  $\Sigma_S$  - **Mon**, as defined by Borthelle et al. [2020], is isomorphic to S - **DBAlg** – in fact essentially equal, since the only difference lies in the difference between a family  $(M^{|ar(o)|} \to M)_{o \in O}$  of operations and its cotupling  $\Sigma_{o \in O} M^{|ar(o)|} \to M$ : one could easily adjust the presentation to get an exact match.

First, in §6.1, we briefly recall structurally strong endofunctors. In §6.2, we will then interpret binding signatures as such endofunctors, we recall the category of  $\Sigma$ -monoids, for any structurally strong endofunctor  $\Sigma$ , and establish the announced isomorphism of categories.

# 6.1 Structural strengths

We start by introducing a notion of set equipped with variables and renamings, in Definition 6.3 below. Recalling from Example 2.3 that  $\mathbb{N}$  forms a De Bruijn monad, we have:

*Definition 6.1.* An  $\mathbb{N}$ -module is a set X equipped with an action of the monoid  $\mathbb{N}^{\mathbb{N}}$ . We typically denote the action by  $r: X \times \mathbb{N}^{\mathbb{N}} = X \otimes \mathbb{N} \to X$ .

**Notation 3.** We generally denote r(x, f) by  $x[f]_r$ , or merely x[f] when clear from context.

*Example 6.2.* Any De Bruijn monad X (in particular  $\mathbb{N}$  itself) has a canonical structure of  $\mathbb{N}$ -module given by  $r(x, f) = x[v \circ f]$ .

Definition 6.3.

- A **pointed**  $\mathbb{N}$ -module is an  $\mathbb{N}$ -module (X, r), equipped with a map  $v : \mathbb{N} \to X$  which is a morphism of  $\mathbb{N}$ -modules.
- A morphism of pointed N-modules is a map commuting with action and point, in the obvious sense.
- Let  $\mathbb{N}$  **Mod** $\mathbb{N}$  denote the category of pointed  $\mathbb{N}$ -modules.

Example 6.4. The variables map of any De Bruijn monad makes it a pointed N-module.

We now define a tensor product on  $\mathbb{N}$ -modules. Following [Lack and Street 2014, (8.1)], tensor product of (pointed)  $\mathbb{N}$ -modules is given by the following coequaliser in Set, where  $r_X: X \otimes \mathbb{N} \to X$  denotes the  $\mathbb{N}$ -module structure on X.

$$(X \otimes \mathbb{N}) \otimes Y \xrightarrow{r_X \otimes Y} X \otimes (\mathbb{N} \otimes Y) \xrightarrow{X \otimes \lambda_Y} X \otimes Y \xrightarrow{\kappa_{X,Y}} X \boxtimes Y, \tag{3}$$

where  $\alpha$  denotes the associator of (Set,  $\otimes$ ,  $\mathbb{N}$ ).

By [Lack and Street 2014, Theorem 8.1],  $\mathbb{N}$  - **Mod** is a skew monoidal category (with invertible right unit), and the forgetful functor is monoidal and creates monoids. In fact, this extends to  $\mathbb{N}$  - **Mod** $\mathbb{N}$ , and we define:

Definition 6.5 (Borthelle et al. [2020, Definition 2.11]). A **structural strength** on an endofunctor  $\Sigma : \mathbf{Set} \to \mathbf{Set}$  is a natural transformation  $st_{X,Y} \colon \Sigma(X) \otimes Y \to \Sigma(X \otimes Y)$ , where X is any set and Y is a pointed  $\mathbb{N}$ -module, making the following diagrams commute,

$$\begin{array}{c|c} \Sigma(A) & \Sigma(A) \\ \Sigma(A) \otimes I & \Sigma(A \otimes I) \\ \hline \Sigma(A) \otimes X \otimes Y \xrightarrow{st_{A,X} \otimes Y} \Sigma(A \otimes X) \otimes Y \xrightarrow{st_{A \otimes X}, Y} \Sigma(A \otimes X \otimes Y) \\ \alpha'_{\Sigma(A),X,Y} & & \downarrow \Sigma(\alpha'_{A,X,Y}) \\ \Sigma(A) \otimes (X \boxtimes Y) & \xrightarrow{st_{A,X \boxtimes Y}} \Sigma(A \otimes (X \boxtimes Y)) \end{array}$$

where  $\rho$  denotes the right unit of (Set,  $\otimes$ ,  $\mathbb{N}$ ), and  $\alpha'_{A,X,Y}$  is  $(A \otimes \kappa_{X,Y}) \circ \alpha_{A,X,Y}$ .

#### 6.2 De Bruijn algebras as $\Sigma$ -monoids

Let us now interpret binding signatures as structurally strong endofunctors, and show that the corresponding category of models coincides with De Bruijn algebras.

The main strength of De Bruijn representation, with the current viewpoint, is that we can readily equip the endofunctor  $\Sigma_S$  associated to any binding signature S with a structural strength  $\mathbf{dbs}_S$ , which we call the **De Bruijn** strength prescribed by S on  $\Sigma_S$ .

**Remark 10.** Let us recall that by definition,  $\Sigma_S$  ignores the binding information in S: we have

$$\Sigma_S(X) = \sum_{o \in O} X^{p_o},$$

where  $ar(o) = (n_1^o, \dots, n_{p_o}^o)$  for all  $o \in O$ .

In order to define  $\mathbf{dbs}_S$ , we start by generalising Definition 2.5 from De Bruijn monads to pointed  $\mathbb{N}$ -modules.

*Definition 6.6.* Let (Y, v, r) be a pointed  $\mathbb{N}$ -module. Then:

- Let  $\uparrow_Y : \mathbb{N} \to Y$  map any n to v(n+1).
- For any assignment  $\sigma \colon \mathbb{N} \to Y$ , let

$$\sigma'(0) = v(0) 
\sigma'(n+1) = \sigma(n) [\uparrow].$$

• For any assignment  $\sigma \colon \mathbb{N} \to Y$ , we define by induction on  $n \in \mathbb{N}$ :

$$\sigma^{(0)} = \sigma 
\sigma^{(n+1)} = (\sigma^{(n)})'.$$

Let us first define the De Bruijn strengths of the identity functor.

Definition 6.7. The **first De Bruijn strength** of the identity functor is the map

$$\mathbf{dbs}_{\mathrm{id},X,Y} \colon X \otimes Y \quad \to \quad X \otimes Y \\ (x,\sigma) \quad \mapsto \quad (x,\sigma'),$$

defined for all  $X \in \mathbf{Set}$  and Y a pointed  $\mathbb{N}$ -module.

Proposition 6.8. The first De Bruijn strength is a structural strength on the identity functor.

This may of course by iterated:

*Definition 6.9.* Let the *n*th **De Bruijn strength** of the identity functor, **dbs**<sup>n</sup>, be defined by  $\mathbf{dbs}_{\mathrm{id} \times Y}^{n}(x,\sigma) = (x,\sigma^{(n)})$ .

Proposition 6.10. Structurally strong endofunctors compose, in the sense that if F and G are structurally strong endofunctors, then so is  $G \circ F$ , with structural strength given by the composite

$$G(F(X)) \otimes Y \to G(F(X) \otimes Y) \to G(F(X \otimes Y)).$$

Thus  $id \circ id = id$  is structurally strong, and we have:

Proposition 6.11. Each  $\mathbf{dbs}^n$  is a structural strength on the identity functor.

Let us now extend this to general binding arities:

*Definition 6.12.* For any binding arity  $a = (n_1, \dots, n_p)$ , the **De Bruijn strength dbs**a of a on the functor  $X \mapsto X^p$  is defined by

$$\mathbf{dbs}_{a,X,Y} \colon X^p \otimes Y \quad \to \quad (X \otimes Y)^p \\
((x_1, \dots, x_p), \sigma) \quad \mapsto \quad ((x_1, \sigma^{(n_1)}), \dots, (x_p, \sigma^{(n_p)})),$$

for all sets X and pointed  $\mathbb{N}$ -modules Y.

As promised, the binding condition may be expressed in terms of strengths:

PROPOSITION 6.13. For any binding arity  $a = (n_1, ..., n_p)$  and De Bruijn monad (M, s, v), a map  $o: M^p \to M$  satisfies the a-binding condition iff the following pentagon commutes.

$$X^{p} \otimes X \xrightarrow{\operatorname{dbs}_{a,X,X}} (X \otimes X)^{p} \xrightarrow{s^{p}} X^{p}$$

$$\downarrow o \otimes X \downarrow \qquad \qquad \downarrow o$$

$$X \otimes X \xrightarrow{\qquad \qquad } X$$

$$(4)$$

At last, let us now define the De Bruijn strength of the endofunctor  $\Sigma_S$  induced by an arbitrary binding signature S. Recalling that an element of  $\Sigma_S(X)$  has the form  $(o, (x_1, \dots, x_{p_o}))$  for some  $o \in O$ , we have:

*Definition 6.14.* For any binding signature S = (O, ar), the **De Bruijn strength dbs**<sub>S</sub> of the induced endofunctor  $\Sigma_S$  is defined by  $\mathbf{dbs}_S = \sum_{o \in o} \mathbf{dbs}_{ar(o)}$ , or more concretely

$$\begin{array}{ccc} \Sigma_{S}(X) \otimes Y & \to & \Sigma_{S}(X \otimes Y) \\ ((o, (x_{1}, \dots, x_{p_{o}})), \sigma) & \mapsto & (o, ((x_{1}, \sigma^{(n_{1})}), \dots, (x_{p_{o}}, \sigma^{(n_{p_{o}})}))), \end{array}$$

for all sets X and pointed  $\mathbb{N}$ -modules Y.

PROPOSITION 6.15. The De Bruijn strength of  $\Sigma_S$  is a structural strength.

In order to relate the initial-algebra semantics of §3 to the strength-based approach of Borthelle et al. [2020]; Fiore [2008]; Fiore et al. [1999], let us recall the definition of models in the latter.

*Definition 6.16.* Given a structurally strong endofunctor  $\Sigma$ , a  $\Sigma$ -monoid is an object X, equipped with monoid and  $\Sigma$ -algebra structure, say  $s \colon X \otimes X \to X$ ,  $v \colon \mathbb{N} \to X$ , and  $a \colon \Sigma(X) \to X$ , making the following pentagon commute.

$$\Sigma(X) \otimes X \xrightarrow{\operatorname{dbs}_{S,X,X}} \Sigma(X \otimes X) \xrightarrow{\Sigma(s)} \Sigma(X)$$

$$\downarrow a \\ X \otimes X \xrightarrow{s} X$$
(5)

A morphism of  $\Sigma$ -monoids is a map which is both a monoid and a  $\Sigma$ -algebra morphism.

Let  $\Sigma$  - **Mon** denote the category of  $\Sigma$ -monoids and morphisms between them.

We may at last relate the initial-algebra semantics of §3 with the strength-based approach:

PROPOSITION 6.17. For any binding signature S = (O, ar) and De Bruijn monad (M, s, v) equipped with a map  $o_M : M^p \to M$  for all  $o \in O$  with  $ar(o) = (n_1, ..., n_p)$ , the following are equivalent:

- (i) each map  $o_M: M^p \to M$  satisfies the a-binding condition w.r.t. (s, v);
- (ii) the corresponding map  $\Sigma_S M \to M$  renders the pentagon (5) (with  $\Sigma := \Sigma_S$ ) commutative.

COROLLARY 6.18. For any binding signature S, we have an isomorphism  $\Sigma_S$  - Mon  $\cong S$  - DBAlg of categories over Set.

This readily entails the following (bundled) reformulation of Theorems 2.15 and 3.6.

COROLLARY 6.19. Consider any binding signature S = (O, ar), and let  $DB_S$  denote the initial  $(\mathbb{N} + \Sigma_S)$ -algebra, with structure maps  $v \colon \mathbb{N} \to DB_S$  and  $a \colon \Sigma_S(DB_S) \to DB_S$ . Then:

- (i) There exists a unique substitution map  $s: DB_S \otimes DB_S \to DB_S$  such that
  - the map  $\mathbb{N} \otimes \mathrm{DB}_S \xrightarrow{v \otimes \mathrm{DB}_S} \mathrm{DB}_S \otimes \mathrm{DB}_S \xrightarrow{s} \mathrm{DB}_S$  coincides with the left unit of the skew monoidal structure  $(n, f) \mapsto f(n)$ , and
  - the pentagon (5) (with  $\Sigma := \Sigma_S$ ) commutes.
- (ii) This substitution map turns ( $\mathbf{DB}_S$ , v, s, a) into a  $\Sigma_S$ -monoid.
- (iii) This  $\Sigma_S$ -monoid is initial in  $\Sigma_S$ -Mon.

PROOF. Let Mon(Set) denote the category of monoids in Set for the skew monoidal structure. We have an equality Mon(Set) = DBMnd of categories, and the algebra structure  $\Sigma_S(DB_S) \to DB_S$  is merely the cotupling of the maps  $o_{DB_S}$  of Theorem 2.15. This correspondence translates one statement into the other.

**Remark 11.** This result hints at a potential push-button proof of Theorems 2.15 and 3.6 (and Corollary 6.19). Indeed, it is almost an instance of Borthelle et al. [2020, Theorem 2.15]: the latter is stated for general skew monoidal categories instead of merely **Set**, but does not directly apply in the present setting, because it assumes that the tensor product is finitary in the second argument.

#### 7 MODULE-BASED INTERPRETATION OF THE BINDING CONDITIONS

In the previous section, we have recast the initial-algebra semantics of §3 into the strength-based approach to variable binding [Borthelle et al. 2020; Fiore et al. 1999]. In this section, we present an alternative recasting, into the module-based approach to variable binding [Hirschowitz and Maggesi 2007, 2010]. The present section may safely be skipped, as it is not used in the rest of the paper.

In the context of monads over sets, it is well-known that, for a model X of a signature S, the conditions expressing the compatibility of operations with substitution may be synthetised by saying that the structure map  $\Sigma_S(X) \to X$  is a module morphism with respect to suitable, natural module structures on  $\Sigma_S(X)$  and X, respectively: this interpretation, which involves an operation called **derivation** of modules, goes back at least to Hirschowitz and Maggesi [2007]. Let us now explain how it may be adapted to the framework of the present paper. A main feature is that here derivation of modules does not change the support, hence concerns substitution only. In §7.1, we introduce modules over a De Bruijn monad. In §7.2, we define module derivation. Finally, in §7.3, we present our alternative interpretation of the binding conditions.

#### 7.1 Modules over De Bruijn monads and first-order signatures

There is a general notion of module over a monoid in a monoidal (or skew monoidal see Borthelle et al. [2020]) category, which we do not refer to: we just give the instance we are concerned with. Intuitively, if X is a De Bruijn monad, an X-module is a set that admits substitution of variables by elements of X:

Definition 7.1. For any De Bruijn monad (X, s, v), an X-module is a set A equipped with a map

$$\begin{array}{ccc} A \times X^{\mathbb{N}} & \to & A \\ (a, f) & \mapsto & a[f], \end{array}$$

such that, for all  $a \in A$  and  $f, g \in X^{\mathbb{N}}$ , we have a[f][g] = a[f[g]] and a[v] = a.

Of course, we have:

*Example 7.2.* Any De Bruijn monad X is itself an X-module, with map  $X \times X^{\mathbb{N}} \to X$  given by substitution, which is coherent with our abbreviation.

As algebras for the monad  $-\otimes X$ , cartesian product of sets lifts to X-modules, which yields in particular the right module for specifying application in the  $\lambda$ -calculus:

*Example 7.3.* For any De Bruijn monad X,  $X^2$  is an X-module, with  $(x_1, x_2)[f] = (x_1[f], x_2[f])$ . More generally:

*Definition 7.4.* For any sequence  $A_1, \ldots, A_n$  of X-modules, the cartesian product  $A_1 \times \ldots \times A_n$  is again an X-module, with action given by  $(a_1, \ldots, a_n)[f] = (a_1[f], \ldots, a_n[f])$ .

Viewing the arity of an operation as an *X*-module *A*, compatibility with substitution may be stated by requiring that the structure map  $A \to X$  be a module morphism, in the following sense.

Definition 7.5.

- An *X*-module morphism  $(A, \rho) \to (B, \tau)$ , or  $A \to B$  for short, is a map  $f: A \to B$  which commutes with substitution, in the sense that f(a)[g] = f(a[g]), for all  $a \in A$  and  $g \in X^{\mathbb{N}}$ .
- Let *X* **Mod** denote the category of *X*-modules, with *X*-module morphisms between them.

Proposition 7.6. For any first-order signature S, equipping a De Bruijn monad (X, s, v) with a S-DBAlg structure is equivalent to providing a module morphism  $o_X : X^p \to X$  for each operation o with arity p.

PROOF. The action of *X* on 
$$X^p$$
 is by definition  $X^p \times X^{\mathbb{N}} \to X$ 

$$((x_1, x_2), f) \mapsto (x_1[f], x_2[f])$$

 $((x_1,\ldots,x_p),f) \mapsto (x_1[f],\ldots,x_p[f]).$  Thus, the module morphism condition  $o_X(x_1,\ldots,x_p)[f] = o_X((x_1,\ldots,x_p)[f])$  agrees with the binding condition (2) specialised to first-order signatures.

We now need to generalise this to binding arities. The good news is that these also form modules, as we now show.

#### 7.2 Derivation of substitution for modules

In this subsection, we explain the derivation of modules. This derivation does not change the carrier of the module, hence it acts on the substitution map only. In fact, it acts via the second argument of substitution, namely the assignment, as in §3.

Our starting point is the functor  $- \times X \colon X \operatorname{-}\mathbf{Mod} \to X \operatorname{-}\mathbf{Mod}$  on  $X\operatorname{-}$ modules mapping any A to  $A \times X$ . Let us prove:

PROPOSITION 7.7. The endofunctor  $-\times X$  has a right adjoint mapping A to  $A^{(1)}$ , called the **derivative** of A, where  $A^{(1)}$  has the same carrier as A, with action given by

$$\begin{array}{ccc} A \times X^{\mathbb{N}} & \to & A \\ (a, f) & \mapsto & a[f'], \end{array}$$

where f' is as in Definition 2.5.

Of course we may iterate this endofunctor:

Definition 7.8. Let 
$$A^{(0)} = A$$
, and  $A^{(n+1)} = (A^{(n)})^{(1)}$ .

# 7.3 Interpreting the binding conditions

Starting from a De Bruijn monad X with the corresponding "tautological" X-module X, and combining derivations and cartesian products, we get, for each binding arity  $a := (n_1, \ldots, n_p)$  of length p, a specific X-module  $X^{(a)} := X^{(n_1)} \times \ldots \times X^{(n_p)}$  with carrier  $X^p$ .

They allow us to reformulate the binding conditions as follows:

PROPOSITION 7.9. Let  $a = (n_1, ..., n_p)$  be a binding arity of length p, and (M, s, v) be a De Bruijn monad. Then a map  $o: M^p \to M$  satisfies the a-binding condition w.r.t. (s, v) iff it is an M-module morphism from  $M^{(a)}$  to M.

Summing over the operations of the given binding signature, we get:

PROPOSITION 7.10. For any binding signature S, equipping a De Bruijn monad (X, s, v) with a S-DBAlg structure is equivalent to providing a module morphism  $\sum_{n \in O} X^{(ar(o))} \to X$ .

#### 8 SIMPLY-TYPED EXTENSION

In this section, we extend the framework of §2–3, which is untyped, to the simply-typed case. For this, we fix in the whole section a set  $\mathbb{T}$  of **types**. We follow the same pattern as in §2–3, moving from **Set** to  $\mathbf{Set}^{\mathbb{T}}$ , whose objects we call  $\mathbb{T}$ -**sets**. A morphism  $X \to Y$  is a family  $(X(\tau) \to Y(\tau))_{\tau \in \mathbb{T}}$  of maps.

#### 8.1 De Bruijn T-monads

In this subsection, we define the typed analogue of De Bruijn monads.

The role of  $\mathbb{N}$  will be played in the typed context by the following  $\mathbb{T}$ -set.

*Definition 8.1.* Let  $N \in Set^{T}$  be defined by  $N(\tau) = \mathbb{N}$ .

*Definition 8.2.* Given a  $\mathbb{T}$ -set X, an X-assignment is a morphism  $\mathbb{N} \to X$ . We sometimes merely use "assignment" when X is clear from context.

#### Notation 4.

- We observe that  $\mathbb{T}$ -sets form a cartesian closed category, where the exponential object  $X^Y$  is given by  $(X^Y)(\tau) = X(\tau)^{Y(\tau)}$ .
- We distinguish it from the hom-set by writing the latter [Y, X].
- For any set A and  $\mathbb{T}$ -set X, let  $A \cdot X = \sum_{a \in A} X$  denote the A-fold coproduct of X.

*Example 8.3.* Consider arbitrary  $\mathbb{T}$ -sets X, Y, and Z.

• The  $\mathbb{T}$ -set  $[X,Y] \cdot Z$  is such that for all types  $\tau$ , we have

$$([X,Y] \cdot Z)(\tau) = [X,Y] \cdot Z(\tau) = [X,Y] \times Z(\tau).$$

• The  $\mathbb{T}$ -set  $Y^X \times Z$  is such that for all types  $\tau$ , we have

$$(Y^X \times Z)(\tau) = Y(\tau)^{X(\tau)} \times Z(\tau).$$

We will use the former for generalising substitution to the typed case.

**Notation 5.** For coherence with the untyped case, we tend to write an element of  $([N, Y] \cdot X)(\tau)$  as (x, f), with  $x \in X(\tau)$  and  $f : N \to Y$ .

**Notation 6.** Consider any map  $s: [N, Y] \cdot X \rightarrow Z$ .

• For all  $\tau \in \mathbb{T}$ ,  $x \in X(\tau)$ , and  $g \colon \mathbb{N} \to Y$ , we write  $x[g]_{s,\tau}$  for  $s_{\tau}(x,g)$ , or even x[g] when s and  $\tau$  are clear from context.

• Furthermore, s gives rise to the map  $[N, Y] \cdot X^N \rightarrow Z^N$ 

$$(g, f) \mapsto \tau, n \mapsto f(n)[g]_{s,\tau}.$$

We use similar notation for this map, i.e.,  $f[g]_{s,\tau}(n) := f(n)[g]_{s,\tau}$ , or f[g](n) = f(n)[g] when s and  $\tau$  are clear from context.

The definition of De Bruijn monads generalises almost mutatis mutandis:

*Definition 8.4.* A **De Bruijn**  $\mathbb{T}$ **-monad** is a  $\mathbb{T}$ -set X, equipped with

- a **substitution** morphism  $s : [N, X] \cdot X \to X$ , which takes an element  $x \in X$  and an assignment  $f : N \to X$ , and returns an element x[f], and
- a **variables** morphism  $v: \mathbb{N} \to X$ ,

such that for all  $x \in X$ , and  $f, g: \mathbb{N} \to X$ , we have

$$x[f][g] = x[f[g]]$$
  $v(n)[f] = f(n)$   $x[v] = x.$ 

*Example 8.5.* The  $\mathbb{T}$ -set N itself is clearly a De Bruijn  $\mathbb{T}$ -monad, with variables given by the identity and substitution  $[N,N]\cdot N\to N$  given by evaluation. It is in fact initial in  $DBMnd(\mathbb{T})$ .

*Example 8.6.* The set  $\Lambda_{ST}$  of simply-typed  $\lambda$ -terms with free variables of type  $\tau$  in  $\mathbb{N} \times \{\tau\}$ , considered equivalent modulo  $\alpha$ -renaming, forms a De Bruijn monad. Variables  $\mathbb{N} \to \Lambda_{ST}$  are given by mapping, at any  $\tau$ , any  $n \in \mathbb{N}$  to the variable  $(n, \tau)$ . Substitution  $[\mathbb{N}, \Lambda_{ST}] \cdot \Lambda_{ST} \to \Lambda_{ST}$  is standard, capture-avoiding substitution. One main purpose of this section is to characterise  $\Lambda_{ST}$  by a universal property, and reconstruct it categorically.

# 8.2 Morphisms of De Bruijn T-monads

Definition 8.7. A morphism  $(X, s, v) \to (Y, t, w)$  between De Bruijn  $\mathbb{T}$ -monads is a morphism  $f: X \to Y$  of  $\mathbb{T}$ -sets commuting with substitution and variables, in the sense that for all  $\tau \in \mathbb{T}$ ,  $x \in X(\tau)$ , and  $g: \mathbb{N} \to X$  we have  $f_{\tau}(x[g]) = f_{\tau}(x)[f \circ g]$  and  $f \circ v = w$ .

**Remark 12.** More explicitly, the first axiom says:  $f_{\tau}(s_{\tau}(x,g)) = t_{\tau}(f_{\tau}(x), f \circ g)$ .

PROPOSITION 8.8. De Bruijn  $\mathbb{T}$ -monads and morphisms between them form a category  $\mathbf{DBMnd}(\mathbb{T})$ .

# 8.3 De Bruijn T-monads as relative monads

The presentation based on relative monads extends to the typed setting, by replacing the functor  $\mathbb{N}\colon 1\to \mathbf{Set}$  with  $\mathbf{N}\colon 1\to \mathbf{Set}^{\mathbb{T}}$ , so that  $\mathrm{Lan}_{\mathbf{N}}(X)(Y)\cong [\mathbf{N},Y]\cdot X$ . Thus,  $\mathbf{DBMnd}(\mathbb{T})$  is equivalently the category of monads relative to the functor  $1\to \mathbf{Set}^{\mathbb{T}}$  picking  $\mathbf{N}$ . For the record, let us explicitly introduce the corresponding tensor product.

*Definition 8.9.* For any  $\mathbb{T}$ -sets X and Y, let  $X \otimes Y = [N, Y] \cdot X$ .

**Notation 7.** For coherence with the untyped case, we tend to write an element of  $(X \otimes Y)(\tau)$  as (x, f), with  $x \in X(\tau)$  and  $f : \mathbb{N} \to Y$ .

# 8.4 Initial-algebra semantics

We now adapt the initial-algebra semantics of §3 to the typed case.

Let us start by generalising derivation to the typed case. This relies on a typed form of lifting, which acts on all variables of a given type, leaving all other variables untouched.

Definition 8.10. Let (X, s, v) denote any De Bruijn  $\mathbb{T}$ -monad. We first define a typed analogue  $\uparrow_{@\tau,X}$  of the  $\uparrow$  of Definition 2.5, as below left, and then the **derivative** of any assignment  $\sigma \colon \mathbb{N} \to X$  as below right.

Variable binding and substitution for (nameless) dummies

$$\begin{array}{rclcrcl} (\uparrow_{@\tau,X})_{\tau}(n) & = & v_{\tau}(n+1) & & & \sigma_{\tau}^{(\tau)}(0) & = & v_{\tau}(0) \\ (\uparrow_{@\tau,X})_{\tau'}(n) & = & v_{\tau'}(n) & & (\text{if } \tau \neq \tau') & & \sigma_{\tau}^{(\tau)}(n+1) & = & \sigma_{\tau}(n)[\uparrow_{@\tau,X}] \\ & & & & \sigma_{\tau'}^{(\tau)}(n) & = & \sigma_{\tau'}(n)[\uparrow_{@\tau,X}] & & (\text{if } \tau \neq \tau'). \end{array}$$

Finally, for any sequence  $\gamma = (\tau_1, \dots, \tau_n)$  of types, we define  $\sigma^{(\gamma)}$  inductively, by  $\sigma^{(\varepsilon)} = \sigma$  and  $\sigma^{(\gamma,\tau)} = (\sigma^{(\gamma)})^{(\tau)}$ , where  $\varepsilon$  denotes the empty sequence.

8.4.2 Binding arities and binding conditions. We may now generalise binding arities and the binding conditions to the typed setting.

Definition 8.11.

- A **first-order arity** is a pair  $((\tau_1, \dots, \tau_p), \tau) \in \mathbb{T}^* \times \mathbb{T}$  of a list of types and a type.
- A **binding arity** is a tuple  $a = (((\gamma_1, \tau_1), \dots, (\gamma_p, \tau_p)), \tau)$ , where each  $\gamma_i \in \mathbb{T}^*$  is a list of types, and each  $\tau_i$ , as well as  $\tau$ , are types. In other words,  $a \in (\mathbb{T}^* \times \mathbb{T})^* \times \mathbb{T}$ .
- The first-order arity |a| associated to a is  $((\tau_1, \ldots, \tau_b), \tau) \in \mathbb{T}^* \times \mathbb{T}$ .

**Remark 13.** The arity  $(((\gamma_1, \tau_1), \dots, (\gamma_p, \tau_p)), \tau)$  of an operation  $o \in O$  may be understood as follows:

- $\tau$  is the return type;
- $(\tau_1, \ldots, \tau_p)$  are the argument types;
- each list  $\gamma_i = (\tau_1^i, ..., \tau_{q_i}^i)$  specifies that the ith argument should be considered as binding  $q_i$  variables, of respective types  $\tau_1^i, ..., \tau_{q_i}^i$ .

**Notation 8.** We write any arity  $(((\gamma_1, \tau_1), \dots, (\gamma_p, \tau_p)), \tau)$  as an inference rule  $\frac{\gamma_1 \vdash \tau_1 \quad \dots \quad \gamma_p \vdash \tau_p}{\vdash \tau}$ .

$$\frac{\gamma_1 \vdash \tau_1 \qquad \dots \qquad \gamma_p \vdash \tau_p}{\vdash \tau} .$$

*Example 8.12.* The binding signature for simply-typed  $\lambda$ -calculus has two operations  $lam_{\tau,\tau'}$  and  $app_{\tau,\tau'}$  for all types  $\tau, \tau' \in \mathbb{T}$ , of respective arities  $\frac{\tau \vdash \tau'}{\vdash \tau \to \tau'}$  and  $\frac{\vdash \tau \to \tau'}{\vdash \tau}$ .

This allows us to generalise binding conditions, as follows.

Definition 8.13. Let  $a = (((\gamma_1, \tau_1), \dots, (\gamma_p, \tau_p)), \tau)$  be any binding arity, and M be any set equipped with morphisms  $s : [N, M] \cdot M \to M$  and  $v : N \to M$ . An **operation of binding arity** a is a map  $o : M(\tau_1) \times \ldots \times M(\tau_p) \to M(\tau)$  satisfying the following a-binding condition w.r.t. (s, v):

$$\forall \sigma \colon \mathbf{N} \to M, x_1, \dots, x_p \in M(\tau_1) \times \dots \times M(\tau_p), \quad o(x_1, \dots, x_p)[\sigma] = o(x_1[\sigma^{(\gamma_1)}], \dots, x_p[\sigma^{(\gamma_p)}]). \tag{6}$$

8.4.3 Binding signatures and algebras. Finally, we generalise signatures and their models to the typed setting, and state a typed initiality theorem.

*Definition 8.14.* A **first-order typed signature** consists of a set O of **operations**, equipped with an **arity** map  $ar: O \to \mathbb{T}^* \times \mathbb{T}$ .

Definition 8.15. Consider a first-order signature S := (O, ar).

• An *S*-algebra is a set *X*, together with, for each operation  $o \in O$  with arity  $((\tau_1, \dots, \tau_p), \tau)$ , a map  $o_X : X(\tau_1) \times \dots \times X(\tau_p) \to X(\tau)$ .

• A morphism  $X \to Y$  of S-algebras is a map between underlying sets commuting with operations, in the sense that for each  $o \in O$ , letting  $((\tau_1, \dots, \tau_p), \tau) := ar(o)$ , we have for all  $x_1, \ldots, x_p \in X(\tau_1) \times \ldots \times X(\tau_p), f_{\tau}(o_X(x_1, \ldots, x_p)) = o_Y(f_{\tau_1}(x_1), \ldots, f_{\tau_p}(x_p)).$ 

We denote by *S* - alg the category of *S*-algebras and morphisms between them.

Definition 8.16.

- A  $\mathbb{T}$ -binding signature consists of a set O of operations, equipped with an arity map  $O \to (\mathbb{T}^* \times \mathbb{T})^* \times \mathbb{T}$ .
- The first-order signature |S| associated with a binding signature S := (O, ar) is |S| := (O, |ar|), where  $|ar|: O \to \mathbb{T}^* \times \mathbb{T}$  maps any  $o \in O$  to |ar(o)|.

Let us now present the notion of De Bruijn *S*-algebra:

*Definition 8.17.* Consider any  $\mathbb{T}$ -binding signature S := (O, ar).

- A **De Bruijn** S-algebra consists of a De Bruijn  $\mathbb{T}$ -monad (X, s, v), together with, for all  $o \in O$ , an operation  $o_X$  of binding arity ar(o).
- A morphism of De Bruijn S-algebras is a map  $f: X \to Y$  between underlying sets, which is a morphism both of De Bruijn monads and of |S|-algebras.

We denote by *S* - **DBAlg** the category of De Bruijn *S*-algebras and morphisms between them.

In order to extend the initiality theorem to the typed case, we need to define the endofunctor induced by a T-binding signature:

Definition 8.18 (Induced endofunctor).

• For any  $\tau \in \mathbb{T}$ , let  $\mathbf{y}_{\tau}$  denote the  $\mathbb{T}$ -set defined by  $\mathbf{y}_{\tau}(\tau) = 1$ 

$$\mathbf{y}_{\tau}(\tau') = \emptyset \quad (\text{if } \tau' \neq \tau).$$

- The endofunctor  $\Sigma_a$  induced by any arity  $a = \begin{bmatrix} v_{\tau}(\tau') & = & \emptyset & (\text{if } \tau' \neq \tau). \\ \frac{\tau_1^1, \dots, \tau_{q_1}^1 + \tau_1}{1} & \dots & \tau_1^p, \dots, \tau_{q_p}^p + \tau_p \end{bmatrix}$  is
  - defined by  $\Sigma_a(X) = (X(\tau_1) \times \ldots \times X(\tau_p)) \cdot \mathbf{y}_{\tau}$ . Thus, a  $\Sigma_a$ -algebra is a  $\mathbb{T}$ -set X equipped with a morphism  $(X(\tau_1) \times ... \times X(\tau_p)) \cdot y_{\tau} \to X$ , or equivalently a map  $X(\tau_1) \times ... \times X(\tau_p) \to X(\tau)$ .
- The endofunctor  $\Sigma_S$  induced by any  $\mathbb{T}$ -binding signature S = (O, ar) is defined by

$$\Sigma_S(X) = \sum_{o \in O} \Sigma_{ar(o)}(X).$$

Theorem 8.19. For any  $\mathbb{T}$ -binding signature S, let  $DB_S$  denote the initial  $(N + \Sigma_S)$ -algebra, with structure maps  $v : \mathbb{N} \to DB_S$  and  $a : \Sigma_S(DB_S) \to DB_S$ , inducing maps  $o_{DB_S} : DB_S(\tau_1) \times ... \times$  $DB_S(\tau_p) \to DB_S(\tau)$  for all  $o \in O$  with  $ar(o) = (((\gamma_1, \tau_1), \dots, (\gamma_p, \tau_p)), \tau)$ . Then:

- (i) There exists a unique map  $s: [N, DB_S] \cdot DB_S \rightarrow DB_S$  such that
  - for all  $\tau \in \mathbb{T}$ ,  $n \in \mathbb{N}$ , and  $f : \mathbb{N} \to DB_S$ ,  $s_{\tau}(v(n), f) = f_{\tau}(n)$ , and
  - for all  $o \in O$ , the map  $o_{DB_S}$  satisfies the ar(o)-binding condition w.r.t. (s, v).
- (ii) This map turns ( $DB_S$ , v, s, a) into a De Bruijn S-algebra.
- (iii) This De Bruijn S-algebra is initial in S-DBAlg.

#### Application: values in simply-typed $\lambda$ -calculus

While we saw in Example 8.12 that the De Bruijn monad of simply-typed  $\lambda$ -calculus terms admits a simple signature, there is another relevant, related monad, whose elements at any type are values of that type. (Indeed, values are closed under value substitution.) For this monad, the situation is more complex, as already exposed in Hirschowitz et al. [2021a].

First of all, let us consider application binary trees, i.e., proof derivations generated by the

following rules, 
$$\frac{\Gamma \vdash_{BT} \sigma \to \tau \qquad \Delta \vdash_{BT} \sigma}{\Gamma, \Delta \vdash_{BT} \tau}$$

where  $\Gamma$ ,  $\Delta$  denotes concatenation of lists of simple types. Thus a proof of  $\Gamma \vdash_{BT} \tau$  is essentially a simply-typed term involving only application, with one, linearly used free variable for each type in  $\Gamma$ , in the same order.

*Definition 8.20.* Let  $BT_{\sigma}^{\Gamma}$  denote the set of such application binary trees with conclusion  $\Gamma \vdash_{BT} \sigma$ .

We then take as binding signature  $S_{\lambda_v}$  for simply-typed values the one with one operation  $L_{\pi,\sigma}$ of arity  $\frac{\sigma \vdash \tau_1}{\sigma \to \tau}$  for each simple type  $\sigma$  and application binary tree  $\pi \in BT_{\tau}^{\tau_1,\dots,\tau_n}$ .

*Example 8.21.* For a simple example, if  $\pi$  is merely the axiom  $\tau \mapsto \tau$ , then  $L_{\pi,\sigma}$  has the arity  $\frac{\sigma \vdash \tau}{\vdash \sigma \to \tau} \text{ of } \lambda\text{-abstraction. In this case, } L_{\pi,\sigma} \text{ is thought of as forming } \lambda x : \sigma.v^{\tau} \text{ from any value } v \text{ of } \lambda v = 0$ type  $\tau$  with an additional variable of type  $\sigma$ .

*Example 8.22.* For a less trivial, yet basic example, if  $\pi$  is

$$\frac{\tau_1 \to \tau_2 \vdash_{BT} \tau_1 \to \tau_2 \qquad \tau_1 \vdash_{BT} \tau_1}{\tau_1 \to \tau_2, \ \tau_1 \vdash_{BT} \tau_2} \ , \qquad \text{then } L_{\pi,\sigma} \text{ has arity} \qquad \frac{\sigma \vdash \tau_1 \to \tau_2 \qquad \sigma \vdash \tau_1}{\sigma \to \tau_2} \ \cdot$$

This operation is thought of as forming  $\lambda x : \sigma.(f^{\tau_1 \to \tau_2} a^{\tau_1})$  from values f and a.

By Theorem 8.19, the initial De Bruijn  $S_{\lambda_n}$ -algebra has as carrier the initial algebra for the induced endofunctor, which is by construction the subset of values.

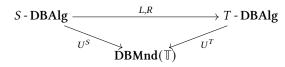

#### 9 EQUATIONS

In this section, we introduce a notion of equational theory for specifying (typed) De Bruijn monads, following ideas from Fiore and Hur [2009]. We start with an elementary presentation, and then give a module-based one.

#### **Elementary presentation**

Definition 9.1. A De Bruijn equational theory consists of

- two binding signatures S and T, and
- two functors L, R: S  $DBAlg \rightarrow T$  DBAlg over  $DBMnd(\mathbb{T})$ , i.e., making the following diagram commute serially, where  $U^S$  and  $U^T$  denote the forgetful functors.

*Example 9.2.* Recalling the binding signature  $S_{\Lambda}$  for  $\lambda$ -calculus from Example 2.12, let us define a De Bruijn equational theory for β-equivalence. We take  $T_{\beta} = (1, 0)$ , and for any De Bruijn  $S_{\Lambda}$ -algebra X

- L(X) has as structure map  $X^2 \rightarrow X$   $(e_1, e_2) \mapsto \operatorname{app}(\operatorname{lam}(e_1), e_2)$  R(X) has as structure map  $X^2 \rightarrow X$   $(e_1, e_2) \mapsto e_1[e_2 \cdot \operatorname{id}].$

(Here  $e_2$  · id denotes the assignment  $0 \mapsto e_2$ ,  $n + 1 \mapsto v(n)$ .)

*Definition 9.3.* Given an equational theory E = (S, T, L, R), a De Bruijn E-algebra is a De Bruijn S-algebra X such that L(X) = R(X).

Let E - **DBAlg** denote the category of E-algebras, with morphisms of De Bruijn S-algebras between them.

**Remark 14.** The category E - **DBAlg** is an equaliser of L and R in **CAT**.

Let us now turn to characterising the initial De Bruijn *E*-algebra, for any De Bruijn equational theory *E*. For this, we introduce the following relation.

Definition 9.4. For any De Bruijn equational theory E = (S, T, L, R), with S = (O, ar) and T = (O, ar'), let  $\mathbf{DB}_S$  denote the initial  $(\mathbf{N} + \Sigma_S)$ -algebra. We define  $\sim_E$  to be the smallest equivalence relation on  $\mathbf{DB}_S$  satisfying the following rules,

$$\frac{e_1 \sim_E e'_1 \quad \dots \quad e_q \sim_E e'_q}{o'_{L(\mathrm{DB}_S)}(e_1, \dots, e_p)} \qquad \frac{e_1 \sim_E e'_1 \quad \dots \quad e_q \sim_E e'_q}{o_{\mathrm{DB}_S}(e_1, \dots, e_q) \sim_E o_{\mathrm{DB}_S}(e'_1, \dots, e'_q)}$$

for all  $e, e_1, \ldots$  in  $DB_S, o' \in O'$  with |ar'(o')| = p, and  $o \in O$  with |ar(o)| = q.

*Example 9.5.* For the equational theory of Example 9.2, the first rule instantiates precisely to the  $\beta$ -rule, while the second enforces congruence.

THEOREM 9.6. For any equational theory E = (S, T, L, R), E - **DBAlg** admits an initial object, whose carrier set is the quotient  $\mathbf{DB}_S/\sim_E$ .

PROOF. This has been mechanised in Coq: existence is called quotsyntax.ini\_morE\_model\_mor, while unicity is called quotsyntax.ini\_morE\_unique.

*Example 9.7.* The initial model for the equational theory of Example 9.2 is the quotient of *λ*-terms in De Bruijn representation by  $\beta$ -equivalence.

**Remark 15.** In [Hirschowitz et al. 2021b, §9], we mention an equivalent way of defining De Bruijn equational theories in terms of modules.

#### 9.2 Module-based presentation

In this section, we mention an equivalent way of defining De Bruijn equational theories in terms of modules, which will be useful below. In the typed case, for any De Bruijn  $\mathbb{T}$ -monad X, it is convenient to define a "heterogeneous" notion of X-module:

Definition 9.8. For any object M of any category C with coproducts, and  $\mathbb{T}$ -set X, let  $M \rtimes X = [N, X] \cdot M$  (recall that  $N \in \mathbf{Set}^{\mathbb{T}}$  is defined by  $\mathbf{N}(\tau) = \mathbb{N}$ ).

Definition 9.9.

• Let  $\mathbf{a}_{M,X,Y} \colon (M \rtimes X) \rtimes Y \to M \rtimes (X \otimes Y)$  denote the composite

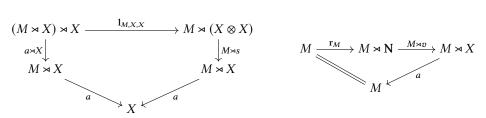

$$[\mathbf{N}, X] \cdot [\mathbf{N}, Y] \cdot M \cong ([\mathbf{N}, X] \times [\mathbf{N}, Y]) \cdot M \rightarrow [\mathbf{N}, [\mathbf{N}, Y] \cdot X] \cdot M,$$

where the involved map  $[N, X] \times [N, Y] \rightarrow [N, [N, Y] \cdot X]$  sends any (f, g) to  $N \xrightarrow{f} X \xrightarrow{in_g} [N, Y] \cdot X$ .

• Let  $\mathbf{r}_M \colon M \to M \rtimes \mathbf{N}$  denote  $M \xrightarrow{in_{\mathrm{id}_{\mathbf{N}}}} [\mathbf{N}, \mathbf{N}] \cdot M$ .

*Definition 9.10.* For any De Bruijn  $\mathbb{T}$ -monad (X, s, v) and category C with coproducts, a C-valued X-module is an object  $M \in \mathbb{C}$ , equipped with an action  $a \colon M \rtimes X \to M$  making the following diagrams commute.

Variable binding and substitution for (nameless) dummies

An X-module morphism is a morphism between underlying objects that commutes with action. Let X - Mod(C) denote the category of C-valued X-modules and morphisms between them.

**Remark 16.** When C = Set, denoting the action by  $(m, f) \mapsto m[f]$ , the axioms become: m[f][g] = m[f[g]] and m[v] = m for all  $f, g: N \to X$  and  $m \in M$ .

Example 9.11.

- Each  $X(\tau)$  is a set-valued X-module, with action given by substitution at  $\tau$ .
- For any  $\gamma \in \mathbb{T}^*$ , if M is any C-valued X-module, then let  $M^{(\gamma)}$  denote the C-valued X-module consisting of
  - the same underlying set *M*, and
  - the action given by  $(m, f) \mapsto m[f^{(\gamma)}]$ , or more generally

$$[\mathbf{N}, X] \cdot M \xrightarrow{(-)^{(\gamma)} \cdot M} [\mathbf{N}, X] \cdot M \xrightarrow{a} M.$$

*Definition 9.12.* A **modular equational theory** consists of two typed binding signatures *S* and *T* as before, plus, for each operation *o* from *T* with arity

$$\frac{\gamma_1 \vdash \tau_1 \qquad \dots \qquad \gamma_p \vdash \tau_p}{\vdash \tau}$$

and De Bruijn S-algebra X, two maps

$$L_X^o, R_X^o: X^{(\gamma_1)}(\tau_1) \times \ldots \times X^{(\gamma_p)}(\tau_p) \longrightarrow X(\tau)$$

in X - Mod(Set), which are natural in X in the sense that for all morphisms  $f: X \to Y$  in S - DBAlg, the following square commutes serially.

$$X^{(\gamma_{1})}(\tau_{1}) \times \ldots \times X^{(\gamma_{p})}(\tau_{p}) \xrightarrow{f_{\tau_{1}}^{(\gamma_{1})} \times \ldots \times f_{\tau_{p}}^{(\gamma_{p})}} Y^{(\gamma_{1})}(\tau_{1}) \times \ldots \times Y^{(\gamma_{p})}(\tau_{p})$$

$$L_{X}^{o} \swarrow R_{X}^{o} \qquad L_{Y}^{o} \swarrow R_{Y}^{o}$$

$$X(\tau) \xrightarrow{f} Y(\tau)$$

We may also reformulate models:

Definition 9.13. A **modular model** of a modular equational theory (S, T, L, R) is a De Bruijn S-algebra X for which  $L_X^o = R_X^o$  for all operations o from T.

Proposition 9.14. Equational theories and modular equational theories are in one-to-one correspondence, and the model categories coincide on the nose.

PROOF. Straightforward by unfolding definitions.

# 10 DE BRUIJN TRANSITION MONADS

In this section, following [Ahrens et al. 2020; Hirschowitz et al. 2020], we extend De Bruijn monads to a notion of programming language, which we then equip with a notion of signature.

# 10.1 A simple notion of programming language

Let us first introduce our notion of programming language. It is based on two sets  $\mathbb{P}$  and  $\mathbb{S}$ , respectively of **program types** and **state types**.

PROPOSITION 10.1. For any  $\mathbb S$ -set M and De Bruijn  $\mathbb P$ -monad (X,s,v), each  $(M\rtimes X)(\sigma)$  forms a (free) X-module valued in  $\mathbb S$ -sets, in the sense of Definition 9.10, with action

$$\begin{array}{ccc} (M(\sigma) \times [\mathbf{N}, X]) \times [\mathbf{N}, X] & \to & M(\sigma) \times [\mathbf{N}, X] \\ ((m, f), g) & \mapsto & (m, f[g]). \end{array}$$

Definition 10.2. A **De Bruijn transition monad** consists of

- a De Bruijn  $\mathbb{P}$ -monad X,
- S-set valued X-modules  $M_1$ ,  $M_2$ , and R, and
- an *X*-module morphism  $R \to M_1 \times M_2$ .

*Example 10.3.* Taking  $\mathbb{P} = \mathbb{S}$  to be the set of simple types over a fixed set of base types, we can take

- $X(\tau)$  to consist of simply-typed values of type  $\tau$ ; this is a monad because values are stable under value substitution;
- $M_1(\tau)$  to consist of general terms, which are also stable under value substitution;
- $M_2 = X$ ; and
- $R(\tau)$  to consist of all big-step evaluation proofs between a term and a value of type  $\tau$ , which are again stable under value substitution.

Of course the X-module morphism  $R \to M_1 \times M_2$  maps any evaluation proof to its source and target.

# 10.2 Registers of signatures

In Hirschowitz et al. [2020], a general, very simple framework for notions of signatures is introduced. Let us briefly recall it here.

Definition 10.4.

- A **semantic signature** over a category C is a category E with initial object, equipped with a **forgetful** functor to C.
- The class of semantic signatures over a category C is denoted by UR<sub>C</sub>.
- A **register** *R* over C consists of
  - a set **Sig**<sub>R</sub> of **signatures**, together with
  - a **semantics** map  $sem_R: Sig_R \to UR_C$  sending each signature to a semantic signature.

Definition 10.5. If  $\operatorname{sem}_R(S)$  is the forgetful functor  $U \colon E \to \mathbb{C}$ , we denote the initial object of E by  $S^{\circledast}$ , and  $U(S^{\circledast})$  by  $S^{\star}$ . Thus, the former is the initial model, while the latter is its "carrier", an object of  $\mathbb{C}$ .

We have already seen a register; let us make this official:

*Definition 10.6.* The register  $ET(\mathbb{T})$  has

**Signatures** De Bruijn equational theories with types in  $\mathbb{T}$  (§9) as signatures, and **Semantics** its semantics map sends any E to E-DBAlg, with the obvious forgetful functor to DBMnd( $\mathbb{T}$ ).

**Validity proof:** By Theorem 9.6.

In the following sections, we design a register for De Bruijn transition monads, whose signatures will allow us to efficiently specify relevant programming languages.

A signature will consist of four components, from three different registers:

- a signature *E* for a De Bruijn monad (*E* will be a De Bruijn equational theory);
- signatures  $E_1$  and  $E_2$  for  $E^*$ -modules; and
- a signature  $E_R$  for an object of  $E^*$   $\mathbf{Mod}_f(\mathbf{Set}^{\mathbb{S}})/E_1^* \times E_2^*$ .

For the first register, we take as signatures De Bruijn equational theories, the semantics of any *E* being *E* - **DBAlg**, as expected.

# 10.3 Signatures for modules over a De Bruijn monad

*Definition 10.7.* Let **Facet** =  $(\mathbb{P} + \mathbb{S}) \times \mathbb{P}^*$  denote the set of pairs  $\varphi = (\zeta, (p_1, \dots, p_n))$  with  $\zeta$  a program or state type, and  $p_1, \dots, p_n$  a sequence of program types.

Definition 10.8. A module arity is a pair of a facet and a state type, i.e., an element of Facet\* × S.

#### Notation 9.

- For any state type  $\sigma \in \mathbb{S}$ , we denote by  $\Theta_{\sigma}^{(p_1,\ldots,p_n)}$  the facet  $(\sigma,(p_1,\ldots,p_n))$ .
- For any program type  $p \in \mathbb{P}$ , we denote by  $\mathbf{I}_p^{(p_1,\ldots,p_n)}$  the facet  $(p,(p_1,\ldots,p_n))$ .
- We omit the parentheses when  $p_1, \ldots, p_n$  is the empty sequence.
- We write  $\varphi_1 \times \ldots \times \varphi_n \to \Theta_{\sigma}$  for the module arity  $((\varphi_1, \ldots, \varphi_n), \sigma)$ .

*Definition 10.9 (Binding signatures for X-modules).* Given a De Bruijn monad X, an X-binding signature consists of a set O of operations, equipped with an arity map  $ar: O \to \mathbf{Facet}^* \times \mathbb{S}$ .

*Example 10.10.* Recalling the value monad of §8.5, say  $\mathcal{L}_v$ , we would like to view the set of all terms as an  $\mathcal{L}_v$ -module. For this, we introduce the  $\mathcal{L}_v$ -binding signature  $S_{\text{app}}$  with operations

$$\operatorname{val}_{\tau} \colon I_{\tau} \to \Theta_{\tau}$$
 and  $\operatorname{app}_{\sigma,\tau} \colon \Theta_{\sigma \to \tau} \times \Theta_{\sigma} \to \Theta_{\tau}$ ,

for all types  $\sigma$  and  $\tau$ . We will see below that this signature specifies the family of simply-typed terms, viewed as an  $\mathcal{L}_v$ -module.

Definition 10.11 (Models).

• We define the interpretation  $\Sigma_{\varphi}^X(M)$  of any facet  $\varphi$  on any X-module M over any De Bruijn monad X by:

monad 
$$X$$
 by:  

$$- \sum_{\substack{\Gamma_p^{(p_1,\dots,p_n)} \\ \Theta_{\sigma}^{(p_1,\dots,p_n)}}}^{X}(M) = X_p^{(p_1,\dots,p_n)}, \text{ and }$$

$$- \sum_{\substack{\Theta_{\sigma}^{(p_1,\dots,p_n)} \\ \Theta_{\sigma}^{(p_1,\dots,p_n)}}}^{X}(M) = M_{\sigma}^{(p_1,\dots,p_n)}.$$

- Given an X-binding signature S = (O, ar), an S-algebra is an S-set valued X-module M equipped with a morphism  $o_M : \Sigma_{\varphi_1}^X(M) \times \ldots \times \Sigma_{\varphi_n}^X(M) \to M_{\sigma}$ , for each  $o \in O$ , where  $ar(o) = ((\varphi_1, \ldots, \varphi_n), \sigma)$
- An *S*-algebra morphism is an *X*-module morphism which commutes with operations.
- Let *S* alg denote the category of *S*-algebras and morphisms between them.

We may at last introduce our register for modules over a given De Bruijn monad.

Definition 10.12. The register  $\mathbf{ModReg}(X)$  has

**Signatures** as signatures all *X*-binding signatures, and

**Semantics** the semantics of any *X*-binding signature *S* is *S* - alg (over *X* - Mod).

**Validity proof:** The category X - **Mod** is the category of algebras for the monad  $M \mapsto M \otimes X$  on sets. Since the monad is  $\aleph_1$ -accessible, X - **Mod** is locally  $\aleph_1$ -presentable. Furthermore, for any X-binding signature S, S - **alg** is the category of algebras for the induced endofunctor  $\Sigma_S^X$  on X - **Mod**, whose definition should be clear from Definition 10.11. This endofunctor being finitary, the forgetful functor S - **alg**  $\to X$  - **Mod** admits a left adjoint, and hence an inital object, as desired.

Let us now characterise the initial model of an *X*-binding signature.

Definition 10.13.

- The functor  $F_{\varphi}^X$ : Set  $\to$  Set induced by any facet  $\varphi$  is defined by  $-F_{\mathbf{I}_p^{(\rho_1,\dots,\rho_n)}}^X(M)=X_p$  and  $-F_{\Theta_{\sigma}^{(\rho_1,\dots,\rho_n)}}^X(M)=M_{\sigma}$ .
- The functor  $F^X_{(\varphi_1,\ldots,\varphi_p),\sigma}$ : Set  $\to$  Set induced by any module arity  $((\varphi_1,\ldots,\varphi_p),\sigma)$  is defined by  $-F^X_{(\varphi_1,\ldots,\varphi_p),\sigma}(M)(\sigma) = F^X_{\varphi_1}(M) \times \ldots \times F^X_{\varphi_p}(M) \text{ and } \\ -F^X_{(\varphi_1,\ldots,\varphi_p),\sigma}(M)(\sigma') = \emptyset \text{ if } \sigma' \neq \sigma.$
- The functor  $F_S^X : \mathbf{Set} \to \mathbf{Set}$  induced by any X-binding signature S = (O, ar) is

$$F_S^X(M) = \sum_{o \in O} F_{ar(o)}^X(M).$$

Proposition 10.14. Consider any X-binding signature S.

- The initial  $F_S^X$ -algebra possesses a unique X-module structure turning it into an S-algebra.
- This S-algebra is initial.

*Example 10.15.* In Example 10.10, we announced that the signature  $S_{\text{app}}$  specifies the family of all terms as an  $\mathcal{L}_v$ -module. Indeed, the induced endofunctor on sets is determined by:

$$\Sigma_{S_{\text{app}}}^{\mathcal{L}_{v}}(M)(\sigma) = \mathcal{L}_{v}(\sigma) + \sum_{\tau} M(\tau \to \sigma) \times M(\tau).$$

By Proposition 10.14, the initial  $S_{app}$ -algebra thus has as carrier the family of application binary trees with leaves in values, which is in one-to-one correspondence with that of terms.

#### 10.4 Signatures for transition rules

We have defined the first two registers announced in the end of §10.2. Let us now introduce the last one. For this, let us fix a De Bruijn monad X, together with X-modules  $M_1$  and  $M_2$ . We wish to design a register for X -  $\mathbf{Mod}/M_1 \times M_2$ .

The idea here is to model a transition rule as follows:

- organise the "metavariables" into a set-valued *X*-module *V*,
- describe the conclusion as a module morphism  $V \to (M_1 \times M_2)_{\tau}$ , for some  $\tau \in \mathbb{S}$ , and
- describe each premise as a module morphism of the form  $V \to (M_1 \times M_2)_{\sigma}^{(\gamma)}$ , for a suitable  $(\gamma, \sigma) \in \mathbb{T}^* \times \mathbb{T}$ .

Let us first follow this procedure on an example, the left application rule in simply-typed  $\lambda$ -calculus:

$$\frac{e_1 \to e_1'}{e_1 \ e_2 \to e_1' \ e_2} \ (AppL) \cdot$$

We first of all recall the relevant De Bruijn monad  $\Lambda_{\rm ST}$  from Example 8.6, and take  $M_1=M_2=\Lambda_{\rm ST}$ , since reduction in the simply-typed  $\lambda$ -calculus relates mere terms. Now for the rule, it is implicitly parameterised over the (related) types of  $e_1$  (and  $e_1'$ ) and  $e_2$ . Let us fix them by assuming  $e_1, e_1': \sigma \to \tau$  and  $e_2: \sigma$ , potentially with other free variables. Accordingly, we take  $V = \Lambda_{\rm ST}(\sigma \to \tau)^2 \times \Lambda_{\rm ST}(\sigma)$ . We then describe the conclusion and premise.

• The conclusion is the morphism

$$V \to (\Lambda_{\rm ST}(\sigma \to \tau) \times \Lambda_{\rm ST}(\sigma))^2 \xrightarrow{{\rm app}_{\sigma,\tau} \times {\rm app}_{\sigma,\tau}} \Lambda_{\rm ST}(\tau)^2.$$

• The premise is the projection  $V \to \Lambda_{ST}(\sigma \to \tau)^2$ .

It is probably clear to the reader that the morphisms

$$\Lambda_{\rm ST}(\sigma \to \tau)^2 \leftarrow V \to \Lambda_{\rm ST}(\tau)^2$$

we just defined are related to the (APPL) rule, but maybe not exactly how. Let us now explain this. The point is that the morphisms induce an endofunctor  $\Sigma_{\text{APPL}}$  on  $\Lambda_{\text{ST}}$  -  $\mathbf{Mod}/\Lambda_{\text{ST}}^2$ , given for any object  $R \to \Lambda_{\text{ST}}^2$  over  $\Lambda_{\text{ST}}^2$  by

- evaluating at  $\sigma \to \tau$  to get a morphism  $R(\sigma \to \tau) \to \Lambda_{ST}(\sigma \to \tau)^2$ ;
- pulling back the obtained morphism along the premise morphism  $V \to \Lambda_{ST}(\sigma \to \tau)^2$  to get a morphism  $R' \to V$ ; and finally
- post-composing with the conclusion morphism  $V \to \Lambda_{ST}(\tau)^2$  to get a morphism  $R' \to \Lambda_{ST}(\tau)^2$ ,

all as in the following diagram.

$$R(\sigma \to \tau) \longleftarrow R'$$

$$\downarrow \qquad \qquad \downarrow$$

$$\Lambda_{ST}(\sigma \to \tau)^2 \longleftarrow V \longrightarrow \Lambda_{ST}(\tau)^2$$

The intuition is that R' is the set of instances of the premise, each instance lying over the potential conclusion in  $\Lambda_{ST}(\tau)^2$ .

A model of the rule is thus an  $R \to \Lambda_{ST}^2$  equipped with a map  $R' \to R$  over  $\Lambda_{ST}^2$ , providing a witness that for each instance of the premise the corresponding conclusion is satisfied.

Equivalently, it is  $\Sigma_{AppL}$ -algebra structure.

Let us now formalise all this. We first introduce a notion of rule, then define the endofunctor induced by a rule, and finally our register for transition relations, whose signatures are families of rules.

*Definition 10.16.* Given a De Bruijn monad X and S-valued X-modules  $M_1$  and  $M_2$ , a **rule** over  $(X, M_1, M_2)$  consists of

- a conclusion type  $\tau \in \mathbb{S}$ ,
- a set-valued X-module V of **metavariables**,
- a **conclusion** morphism  $C: V \to (M_1 \times M_2)_{\tau}$ ,
- a finite set *I* of **premise indices**,
- for each  $i \in I$ , a sequent  $(\gamma_i, \tau_i) \in \mathbb{T}^* \times \mathbb{S}$ , together with a **premise** morphism  $P_i : V \to (M_1 \times M_2)_{\tau_i}^{(\gamma_i)}$ .

Definition 10.17. The endofunctor  $\Sigma_{\rho}$ : X -  $\mathbf{Mod}/M_1 \times M_2 \to X$  -  $\mathbf{Mod}/M_1 \times M_2$  induced by a rule  $\rho$  as in Definition 10.16 maps any d:  $R \to M_1 \times M_2$ 

- first to  $\prod_i R_{\tau_i}^{(\gamma_i)} \to \prod_i (M_1 \times M_2)_{\tau_i}^{(\gamma_i)}$ ,
- which it then pulls back along  $\langle P_i \rangle_i \colon V \to \prod_i (M_1 \times M_2)_{\tau_i}^{(\gamma_i)}$ ,

- and postcomposes with  $C: V \to (M_1 \times M_2)_{\tau}$ ,
- before at last embedding this set-valued module morphism into a S-set valued one, mapping  $R' \to (M_1 \times M_2)_{\tau}$  to  $R' \cdot \mathbf{y}_{\tau} \to M_1 \times M_2$ , where

$$R' \cdot \mathbf{y}_{\tau}(\tau) = R'$$
  
 $R' \cdot \mathbf{y}_{\tau}(\sigma) = \emptyset$  (when  $\sigma \neq \tau$ ).

We may now define our register for transition rules:

Definition 10.18. The register  $TR(X, M_1, M_2)$  has

**Signatures** as signatures all families  $(\rho_i)_{i \in I}$  of rules over  $(X, M_1, M_2)$ , and

**Semantics** the semantics of a signature  $(\rho_j)_{j\in J}$  is the category  $(\sum_j \Sigma_{\rho_j})$  - alg of algebras for the induced endofunctor on X -  $\mathbf{Mod}/M_1 \times M_2$ .

Let us conclude with a last rule example, illustrating the possibility of deriving in the premises of a rule.

*Example 10.19.* Let us now consider the  $\xi$ -rule in simply-typed  $\lambda$ -calculus:

$$\frac{e \to e'}{\lambda x. e \to \lambda x. e'} (\xi).$$

As before, the relevant De Bruijn monad is  $\Lambda_{ST}$ , and  $M_1 = M_2 = \Lambda_{ST}$ . Furthermore, the rule is implicitly parameterised over the types of e (and e') and x. Let us fix them by assuming  $x : \sigma \vdash e, e' : \tau$ , potentially with other free variables. Accordingly, we take  $V = \Lambda_{ST}^{(\sigma)}(\tau)^2$ . We then describe the conclusion and premise.

The conclusion is the morphism

$$V = \Lambda_{\mathrm{ST}}^{(\sigma)}(\tau)^2 \xrightarrow{\mathrm{lam}_{\sigma,\tau} \times \mathrm{lam}_{\sigma,\tau}} \Lambda_{\mathrm{ST}}(\sigma \to \tau)^2.$$

• The premise is the identity morphism on *V*, since it precisely relates the two available metavariables.

# 10.5 Signatures for De Bruijn transition monads

Let us now wrap up and define our register for De Bruijn transition monads.

Definition 10.20. The register TM is defined as follows.

**Signatures** Signatures are all tuples  $(E, S_1, S_2, T)$ , where

- E is a De Bruijn equational theory, specifying a De Bruijn monad  $X := E^*$ ,
- $S_1$  and  $S_2$  are X-binding signatures, specifying X-modules  $M_i = S_i^*$ , and
- *T* is a signature in  $TR(X, M_1, M_2)$ , i.e., a family of rules.

**Semantics** The semantic signature associated with any signature  $(E, S_1, S_2, T)$  as above is the category of  $\Sigma_T$ -algebras, i.e.,  $\mathbf{sem}(T)$ , with its forgetful functor to  $X - \mathbf{Mod}/M_1 \times M_2$ .

#### 11 CONCLUSION AND PERSPECTIVES

We have proposed a simple, set-based theory of syntax with variable binding, which associates a notion of model (or algebra) to each binding signature, and constructs a term model following De Bruijn representation. The notion of model features a substitution operation. We have experienced the simplicity of this theory by implementing it in both Coq and HOL Light.

We have furthermore equipped the construction with an initial-algebra semantics, organising the models of any binding signature into a category, and proving that the term model is initial therein.

We hope that this will be useful, first because it provides an induction principle for reasoning on the term model, and also as a framework for operational and denotational semantics.

We have then studied this initial-algebra semantics in a bit more depth, in two directions:

- We have first established a formal link with the mainstream, presheaf-based approach [Fiore et al. 1999], proving that well-behaved models (in a suitable sense on each side of the correspondence) agree up to an equivalence of categories.
- We have then recast the whole initial-algebra semantics into two established, abstract frameworks for syntax with variable binding, one based on strengths [Fiore 2008; Fiore et al. 1999], the other on modules [Hirschowitz and Maggesi 2007, 2010].

Finally, we have shown that our theory extends easily to a simply-typed setting, and smoothly incorporates equations and transitions.

One potentially useful research direction would be to refine the type of assignments, i.e., maps  $\mathbb{N} \to X$ , in the spirit of explicit substitutions [Abadi et al. 1990]. In the long run, this might lead to more usable implementations, thanks to results by Schäfer et al. [2015a].

#### A PROOF SKETCH OF THEOREM 5.22

In this section, we provide a sketch of the proof that the categories  $\Phi_S$  - **Mon**<sub>wb</sub> and S - **DBAlg**<sub>wb</sub> are equivalent, for any signature S.

Let us start by defining functors  $[\mathbb{F}, Set] \to Set$  and  $DBMnd \to [\mathbb{F}, Set]$ .

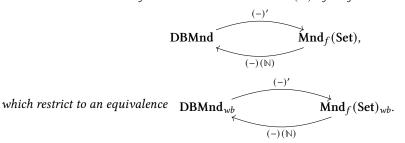

Definition A.1. Let  $(-)(\mathbb{N}): [\mathbb{F}, \mathbf{Set}] \to \mathbf{Set}$  map any  $F: \mathbb{F} \to \mathbf{Set}$  to the coend  $\int^n F(n) \times [n, \mathbb{N}]$ , whose elements we write  $x[\sigma]$ , for all  $x \in F(n)$  and  $\sigma: n \to \mathbb{N}$ . These are equivalence classes of pairs  $(x, \sigma)$  under the equivalence relation generated by  $(x, \sigma \circ f) \sim (f \cdot x, \sigma)$ , for all  $f: n \to p$ ,  $x \in F(n)$ , and  $\sigma: p \to \mathbb{N}$ .

**Remark 17.** Through the equivalence  $[\mathbb{F}, \operatorname{Set}] \simeq [\operatorname{Set}, \operatorname{Set}]_f, X(\mathbb{N})$  really corresponds to evaluation at  $\mathbb{N}$ .

Conversely:

*Definition A.2.* For any De Bruijn monad (X, s, v), let  $X' : \mathbb{F} \to \mathbf{Set}$  map any n to the set of  $x \in X$  with support n.

Proposition A.3. The functors  $X \mapsto X'$  and  $F \mapsto F(\mathbb{N})$  lift to functors

**Remark 18.** We here implicitly transport the notion of well-behavedness from  $[\mathbb{F}, \operatorname{Set}]$  to  $[\operatorname{Set}, \operatorname{Set}]_f$ , and then to  $\operatorname{Mnd}_f(\operatorname{Set})$ . Equivalently, a finitary monad T is well-behaved iff its canonical cocone from  $T(\emptyset)$  is limiting.

PROOF SKETCH.  $\mathbf{Mnd}_f(\mathbf{Set})$  is equivalently the category  $\mathbf{RelMon}$  of monads relative to the full subcategory embedding  $\mathbb{F} \hookrightarrow \mathbf{Set}$ . To see that (-)' lifts to De Bruijn monads, consider any De Bruijn monad (X, s, v), and let  $-[-]: X'(p) \times X'(n)^p \to X'(n)$  map any  $x \in X'(p)$  and  $\sigma: p \to X'(n)$  to

 $x[\bar{\sigma}]$ , where  $\bar{\sigma}(i) = \sigma(i)$  for  $i \in p$ , and  $\bar{\sigma}(j) = v(0)$  for  $j \notin p$ . Similarly, let  $\eta_n \colon n \to X'(n)$  map any  $i \in n$  to v(i). This yields relative monad structure on X', as desired.

Conversely, if T is a relative monad, we define a substitution map  $T(\mathbb{N}) \times T(\mathbb{N})^{\mathbb{N}} \to T(\mathbb{N})$  as follows. For any  $e[\![f]\!] \in T(\mathbb{N})$  and  $\sigma \colon \mathbb{N} \to T(\mathbb{N})$ 

- We start by lifting these functors to functors between **DBMnd** and  $\mathbf{Mnd}_f(\mathbf{Set})$ , using the equivalence of  $\mathbf{Mnd}_f(\mathbf{Set})$  with monads relative to the full embedding  $\mathbb{F} \hookrightarrow \mathbf{Set}$ . The obtained functors restrict to an equivalence on well-behaved objects.
- We then characterise S  $\mathbf{DBAlg}_{wb}$  and  $\Phi_S$   $\mathbf{Mon}_{wb}$  as *inserters* in suitable 2-categories, based on modules, respectively over De Bruijn monads and relative monads. Furthermore, these 2-categories are biequivalent over CAT, so because equivalences of 2-categories preserve inserters, , and finally between S  $\mathbf{DBAlg}_{wb}$  and  $\Phi_S$   $\mathbf{Mon}_{wb}$ .

Let us summarize the two main steps.

- (1) We define relative monads relative to the canonical embedding F → Set (thereafter merely called relative monads) and their modules, and relate them by functors in both directions to De Bruijn monads and their modules. These back and forth functors restricted to well-behaved monads and modules are equivalences.
- (2) Given a binding signature S, we define endofunctors  $S_{rel}$  and  $S_{db}$  on modules for relative monads and De Bruijn monads, so that S-DBAlg (resp.  $\Phi_S$ -Mon) faithfully embeds in the category of  $S_{db}$ -algebras (resp.  $S_{rel}$ -algebras). These endofunctors become isomorphic when restricted to well-behaved monads and modules, through the equivalence exhibited in Step 1. It can then be deduced that the essential images of S-DBAlg<sub>wb</sub>  $\hookrightarrow S_{db}$  alg and  $\Phi_S$ -Mon<sub>wb</sub>  $\hookrightarrow S_{rel}$  alg are equivalent.

# 1.1 Step 1: Relative monads and their modules

**Notation 10.** Let **RelMnd** denote the category of monads relative to the canonical embedding  $\mathbb{F} \to \mathbf{Set}$ , thereafter merely called relative monads. Moreover, given a relative monad (F, bind, ret), we overload the notation -[-] for bind :  $F(n) \times F(m)^n \to F(m)$ .

Definition 1.4. A relative module M over a relative monad  $(F, \operatorname{bind}_F, \operatorname{ret}_F)$  is a functor  $M : \operatorname{Kl}(F) \to \operatorname{Set}$ , where  $\operatorname{Kl}(F)$  is the Kleisli category of F (see [Altenkirch et al. 2015]). We denote the action on morphisms  $M(n) \times F(m)^n \to M(m)$  by -[-].

**Remark 19.** Kl extends to a functor RelMnd  $\rightarrow$  Cat.

**Notation 11.** We denote by RelMod the functor [Kl, Set]: RelMnd<sup>o</sup>  $\rightarrow$  Cat, so that RelMod(F) is the category of relative modules over F. We denote by  $\int$  RelMod  $\rightarrow$  RelMnd the induced fibration: an object of  $\int$  RelMod consists of pairs of a relative monad and a relative module over it.

Similarly, we consider the fibration  $\int \mathbf{DBMod} \to \mathbf{DBMnd}$  of De Bruijn modules (defined, for example, as in Definition 7.1) over De Bruijn monads: an object of  $\int \mathbf{DBMod}$  is a De Bruijn monad X together with a X-module.

These two fibrations have a section that we denote by  $\Theta$ , mapping a monad to itself, as a module over itself.

These two fibrations are related.

PROPOSITION 1.5. Given a De Bruijn-monad (X, s, v), the assignment  $X' : \mathbb{F} \to \mathbf{Set}$  mapping n to the subset  $X'(n) \subset X$  of elements with support X extends to a relative monad  $(X', \mathsf{bind}_X, \mathsf{ret}_X)$  with

• bind<sub>X</sub>:  $X'(n) \times X'(p)^n \to X'(p)$  defined as  $(x, \vec{x'}) \to x[\vec{x'}]$ , where  $\vec{x'} \in X'(p)^n$  is understood as a map  $\mathbb{N} \to X$  mapping i < n to  $x'_i$ , and  $i \ge n$  to v(i);

•  $\operatorname{ret}_X : n \to X'(n)$  defined as  $i \mapsto v(i)$ .

This construction extends to a functor DBMnd  $\rightarrow$  RelMnd.

We can also build a functor in the other direction.

*Definition 1.6.* Given a relative monad (F, bind, ret), let  $F(\mathbb{N})$  denote the set defined as  $\{f[u] | n \in \mathbb{N}, f \in F(n), u : n \to \mathbb{N}\}$  quotiented by the relation  $f[u \circ w] \sim f[\text{ret} \circ w][u]$ , for any  $w : m \to n$ .

LEMMA 1.7. Any tuple  $(t_1[u_1], \ldots t_n[u_n])$  in  $F(\mathbb{N})^n$  can be chosen with  $t_1, \ldots, t_n \in F(m)$  for some  $m \in \mathbb{N}$ , and  $u_1 = \ldots = u_n$ .

PROPOSITION 1.8. Given a relative monad (F, bind, ret), the set  $F(\mathbb{N})$  extends to a De Bruijn monad with  $(F(\mathbb{N}), s_F, v_F)$  where

- t[u][f] is  $t[w][\sigma]$ , with  $w(i)[\sigma] = f(u(i))$ , by Lemma 1.7;
- $v(n) = \operatorname{ret}(n) [i \mapsto i];$

This construction extends to a functor RelMnd  $\rightarrow$  DBMnd.

Similar functors can be constructed at the level of modules, commuting with  $\Theta$ , so that we get a diagram

$$\int \text{RelMod} \longrightarrow \int \text{DBMod}$$

$$\downarrow \qquad \qquad \downarrow$$

$$\text{RelMnd} \longrightarrow \text{DBMnd}$$
(7)

Actually, we argue that horizontal functors restrict to an equivalence on well-behaved objects.

Definition 1.9. A relative monad (resp. module) is well-behaved if the induced functor  $\mathbb{F} \to \mathbf{Set}$  is. A De Bruijn module is well-behaved if each element has a finite support, in the obvious sense.

**Notation 12.** We denote by  $\int DBMod_{wb} \to DBMnd_{wb}$  and  $\int RelMod_{wb} \to RelMnd_{wb}$  the restrictions of the previous fibrations to well-behaved objects.

Proposition 1.10. The horizontal functors in (7) restrict to equivalences on well-behaved objects:

$$\int \operatorname{RelMod}_{wb} \stackrel{\cong}{\longleftarrow} \int \operatorname{DBMod}_{wb} 
\downarrow \qquad \qquad \downarrow 
\operatorname{RelMnd}_{wb} \stackrel{\cong}{\longleftarrow} \operatorname{DBMnd}_{wb}$$
(8)

Lemma 1.11. • If T is a well-behaved relative (resp. De Bruijn) monad, then  $\Theta(T)$  is a well-behaved T-module.

• Given a relative (resp. De Bruijn) monad T, well-behaved modules over T are closed under finite limits and coproducts, which are computed pointwise.

# 1.2 Step 2: Endofunctors on modules induced by a binding signature

Definition 1.12. For any binding signature S, we define endofunctors  $S_{Db}$  on  $\int$  **DBMod** over **DBMnd** and  $S_{Rel}$  on  $\int$  **RelMod** over **RelMod**, mapping a module M to the coproduct of  $M^{(a_1)} \times \ldots \times M^{(a_n)}$ , for each binding arity a in S.

PROPOSITION 1.13. • S-DBAlg is equivalent to the subcategory of  $S_{Db}$ -algebras consisting of X-module morphisms  $S_{Db}(\Theta(X)) \to \Theta(X)$ , for some De Bruijn monad X, and monad morphisms commuting with the algebra structure as morphisms.

•  $\Phi_S$  - Mon is equivalent to the subcategory of  $S_{Rel}$ -algebras consisting of X-module morphisms  $S_{Db}(\Theta(X)) \to \Theta(X)$ , for some relative monad X and monad morphisms commuting with the algebra structure as morphisms.

PROOF SKETCH. The first item follows from Section 7. The second one follows from the equivalence between presheaf-based models and clones [Fiore and Mahmoud 2014; Mahmoud 2011], which closely relates to relative monads.  $\Box$ 

We have a well-behaved variant of this proposition.

Proposition 1.14.  $S_{Db}$  and  $S_{Rel}$  restrict to endofunctors on well-behaved modules. Moreover,

- S-DBAlg<sub>wb</sub> is equivalent to the full subcategory of  $S_{Db}$ -algebras consisting of X-module morphisms  $S_{Db}(\Theta(X)) \to \Theta(X)$ , for some well-behaved De Bruijn monad X, and monad morphisms commuting with the algebra structure as morphisms.
- $\Phi_S$   $\mathbf{Mon}_{wb}$  is equivalent to the subcategory of  $S_{Rel}$ -algebras consisting of X-module morphisms  $S_{Db}(\Theta(X)) \to \Theta(X)$ , for some well-behaved relative monad X, and monad morphisms commuting with the algebra structure as morphisms.

Proposition 1.15. S - **DBAlg**<sub>wb</sub> is equivalent to  $\Phi_S$  - **Mon**<sub>wb</sub>.

PROOF. It is enough to show that  $S_{Rel}$  and  $S_{Db}$  are isomorphic through the equivalences in (8). Note that these equivalences commute with limits, colimits, exponentials (as any equivalence), and thus module derivation since  $M^{(1)}$  is actually the exponential  $M^{\Theta(T)}$  in the category of T-modules.

On a fiber over a monad T,  $S_{Rel}$  and  $S_{Db}$  are defined by the same formula, as coproducts of products of derivative of  $\Theta(T)$ . Hence, they are isomorphic through the equivalence in (8).

# 1.3 Garbage

Definition 1.16. Given a binding signature S, a relative S-algebra is a relative monad (F, bind, ret) equipped with an operation  $o_F: F^{(a_1)} \times \ldots \times F^{(a_n)} \to F$  for each binding arity  $a = (a_1, \ldots, a_n)$  in S, satisfying the a-binding condition. A morphism of relative S-algebras is a morphism of relative monads commuting with operations in the obvious sense.

To avoid confusion, we now sometimes refer to objects of  $\Phi_S$  - **Mon**<sub>wb</sub> as well-behaved De Bruijn S-algebras.

Proposition 1.17. Relative S-algebras form a category which is isomorphic to  $\Phi_S$  - Mon<sub>wb</sub>.

Proof. Citer Arkhor? et encore pas clair qu'il le prouve

PROPOSITION 1.18. Given a De Bruijn-monad (X, s, v), the assignement  $X' : \mathbb{F} \to \mathbf{Set}$  mapping n to the subset  $X'(n) \subset X$  of elements with support X extends to a relative monad  $(X', \mathsf{bind}_X, \mathsf{ret}_X)$  with

- bind<sub>X</sub>:  $X'(n) \times X'(p)^n \to X'(p)$  defined as  $(x, \vec{x'}) \to x[\vec{x'}]$ , where  $\vec{x'} \in X'(p)^n$  is understood as a map  $\mathbb{N} \to X$  mapping i < n to  $x'_i$  and is the identity elsewhere;
- $\operatorname{ret}_X : n \to X'(n)$  defined as  $i \mapsto v(i)$ .

*Definition 1.19.* Given a relative monad (F, bind, ret), let  $F(\mathbb{N})$  denote the set defined as { $f[u] | n \in \mathbb{N}$ ,  $f \in F(n)$ ,  $u : n \to \mathbb{N}$ } quotiented by the relation  $f[u \circ w] \sim w \cdot f$ , for any  $w : \mathbb{N} \to \mathbb{N}$ .

We will systematically exploit the following property of  $F(\mathbb{N})^n$ .

LEMMA 1.20. Any tuple  $(t_1[u_1], \ldots t_n[u_n])$  in  $F(\mathbb{N})^n$  can be chosen with  $t_1, \ldots, t_n \in F(m)$  for some  $m \in \mathbb{N}$ , and  $u_1 = \ldots = u_n$ .

PROPOSITION 1.21. Given a relative monad (F, bind, ret), the set  $F(\mathbb{N})$  extends to a De Bruijn monad with  $(F(\mathbb{N}), s_F, v_F)$  where

- t[u][f] is TODO;
- $v(n) = ret(n)[i \mapsto i];$

PROPOSITION 1.22. (1) Given a relative monad (F, bind, ret) as above, the relative monad on  $F(\mathbb{N})'$  is isomorphic to (F, bind, ret).

(2) Given a well-behaved De Bruijn monad (X, s, v), the De Bruijn monad on  $X'(\mathbb{N})$  is isomorphic to (X, s, v).

Through these maps, operations can be transferred.

Proposition 1.23. Let  $a = (a_1, ..., a_n)$  be a binding arity.

Let (F, bind, ret) be a relative monad, and and  $o: F^{(a_1)} \times \ldots \times F^{(a_n)} \to F$  an operation satisfying the a-binding condition. Then, the function  $F(\mathbb{N})^n \to F(\mathbb{N})$  mapping  $(x_1[\![u]\!], \ldots, x_n[\![u]\!])$  to  $o(x_1, \ldots, x_n)[\![u]\!]$  is well-defined and satisfies the a-binding operations.

Conversely, let (X, s, v) be a De Bruijn monad and  $o: X^{|a|} \to X$  be a morphism of binding arity a. Then, the mapping  $X'^{(a_1)} \times \ldots \times X'^{(a_n)}(n) \to X'(n)$  sending  $(x_1, \ldots, x_n)$  to? satisfied the a-binding operations.

Definition 1.24. Given a binding signature S, the previous propositition induces a map A between well-behaved relative S-algebras and well-behaved De Bruijn S-algebras, and a converse map that we denote by B.

Proposition 1.25. Let S be a binding signature.

- (1) Any well-behaved relative S-algebra F is isomorphic to A(B(F)).
- (2) Any well-behaved De Bruijn S-algebra X is isomorphic to B(A(X)).

Now, the only remaining thing is to show that *A* (or *B*) can be equipped with an action on morphisms such that it induces a full and faithful functor, since an equivalence of categories is exhibited as a full and faithful functor that is essentially surjective (which what the previous proposition just shows).

PROPOSITION 1.26. Let S be a binding signature. Let  $(X_1, s_1, v_1)$  and  $(X_2, s_2, v_2)$  be well-behaved De Bruijn monads equipped with S-algebra structures. Let f be a morphism between them. Then,  $f': X_1' \to X_2'$  mapping x to f(x) defines a relative S-algebra morphism. Moreover, this assignment upgrades A into a fully faithful functor.

Le reste est a supprimer The proof requires to introduce some definitions:

Definition 1.27. Let

- ullet denote the full subcategory of Set spanning finite ordinals,
- $\mathbb{F}^{\bullet}$  denote the full subcategory of  $\mathbb{F}$  spanning non-empty ordinals.
- $\overline{\mathbb{F}}$  denote the full subcategory of **Set** spanning finite ordinals plus  $\mathbb{N}$ ,
- $B(\mathbb{N})$  denote the full subcategory of **Set** on  $\mathbb{N}$ : it has one object, and morphisms are endomaps on  $\mathbb{N}$ .

We now sketch the different proof steps:

- (1) equip  $[\mathbb{F}, \mathbf{Set}]$  and  $[\overline{\mathbb{F}}, \mathbf{Set}]$  with monoidal structure, following [Altenkirch et al. 2015];
- (2) prove that the (full and faithful) right Kan extension  $[\mathbf{B}(\mathbb{N}), \mathbf{Set}] \hookrightarrow [\overline{\mathbb{F}}, \mathbf{Set}]$  has the full subcategory  $[\overline{\mathbb{F}}, \mathbf{Set}]_{wb}$  of  $[\overline{\mathbb{F}}, \mathbf{Set}]$  consisting of functors preserving finite intersections as essential image.
- (3) check that the monoidal structure on  $[\mathbb{F}, \mathbf{Set}]$  and  $[\overline{\mathbb{F}}, \mathbf{Set}]$  restricts to  $[\mathbb{F}, \mathbf{Set}]_{wb}$  and  $[\overline{\mathbb{F}}, \mathbf{Set}]_{wb}$ .

- (4) check that  $[\mathbb{F}, \mathbf{Set}]_{wb} \hookrightarrow [\overline{\mathbb{F}}, \mathbf{Set}]_{wb} \cong [B(\mathbb{N}), \mathbf{Set}]$ , where the first functor is induced by left Kan extension, has  $[B(\mathbb{N}, \mathbf{Set})]_{wb}$  as essential immage.
- (5) exhibit (using suitable Kan extensions) a full reflection  $[\mathbb{F}^{\bullet}, Set] \hookrightarrow [\mathbb{F}, Set]$  and a full coreflection  $[\mathbb{F}^{\bullet}, Set] \hookrightarrow [B(\mathbb{N}), Set]$ , inducing equivalences

$$[\mathbb{F}, \operatorname{Set}]_{wb} \simeq [\mathbb{F}^{\bullet}, \operatorname{Set}] \simeq [\mathbf{B}(\mathbb{N}), \operatorname{Set}]_{wb};$$

- (6) using the results of Lack and Street [2015], deduce that both equivalences are strong monoidal; thus, well-behaved monoids in  $[\mathbb{F}, \mathbf{Set}]$  are equivalent to well-behaved (in a different sense) monoids in  $[\mathbf{B}(\mathbb{N}), \mathbf{Set}]$ ;
- (7) for each signature S, define a pointed strong endofunctor  $\psi_S$  on  $[\mathbb{F}^{\bullet}, \mathbf{Set}]$ , and show that it corresponds to  $\Phi_S$  and  $\Xi_S$ , respectively as pointed strong endofunctors on  $[\mathbb{F}, \mathbf{Set}]_{wb}$  and  $[\mathbf{B}(\mathbb{N}), \mathbf{Set}]_{wb}$ , through the above monoidal equivalence.
- (1) equip  $[\mathbb{F}^{\bullet}, \mathbf{Set}]$  and  $[\mathbf{B}(\mathbb{N}), \mathbf{Set}]$  with monoidal structure, thanks to [Lack and Street 2015];
- (2) prove that S **DBAlg** is equivalent to a category of models for a pointed strong endofunctor  $\Xi_S$  on  $[\mathbf{B}(\mathbb{N}), \mathbf{Set}]$ ;
- (3) exhibit (using suitable Kan extensions) a full reflection  $[\mathbb{F}^{\bullet}, Set] \hookrightarrow [\mathbb{F}, Set]$  and a full coreflection  $[\mathbb{F}^{\bullet}, Set] \hookrightarrow [B(\mathbb{N}), Set]$ , inducing equivalences

$$[\mathbb{F}, \operatorname{Set}]_{wb} \simeq [\mathbb{F}^{\bullet}, \operatorname{Set}] \simeq [\mathbf{B}(\mathbb{N}), \operatorname{Set}]_{wb};$$

- (4) using the results of Lack and Street [2015], deduce that both equivalences are strong monoidal; thus, well-behaved monoids in  $[\mathbb{F}, \mathbf{Set}]$  are equivalent to well-behaved (in a different sense) monoids in  $[\mathbf{B}(\mathbb{N}), \mathbf{Set}]$ ;
- (5) for each signature S, define a pointed strong endofunctor  $\psi_S$  on  $[\mathbb{F}^{\bullet}, \mathbf{Set}]$ , and show that it corresponds to  $\Phi_S$  and  $\Xi_S$ , respectively as pointed strong endofunctors on  $[\mathbb{F}, \mathbf{Set}]_{wb}$  and  $[\mathbf{B}(\mathbb{N}), \mathbf{Set}]_{wb}$ , through the above monoidal equivalence.

The last two items, together with the second item, ensure that  $\Phi_S$  - **Mon** is indeed equivalent to S - **DBAlg**, as desired.

# 1.4 Step 1: the monoidal categories $[\mathbb{F}^{\bullet}, Set]$ and $[B(\mathbb{N}), Set]$

Let us start with the following observation:

Proposition 1.28. Monads relative to some functor  $J \colon \mathbb{C} \to \mathbb{E}$  are equal to monads relative to the composite  $\mathbf{ob}(\mathbb{C}) \to \mathbb{C} \to \mathbb{E}$ .

Proof. The definition does not depend on morphisms in  $\mathbb{C}$ .

COROLLARY 1.29. De Bruijn monads are equal to monads relative to the embedding  $B(\mathbb{N}) \to Set$ .

PROPOSITION 1.30. Let  $J: \mathbb{C} \to \mathbb{E}$  be a full and faithful functor. If the left kan extension functor  $\Sigma_J: [\mathbb{C}, \mathbb{E}] \to [\mathbb{E}, \mathbb{E}]$  along J exist, then  $[\mathbb{C}, \mathbb{E}]$  has a unique (up to isomorphism) skew monoidal structure (given by  $A \otimes B = \sum_J (A) \circ B$ ) such that  $\Delta_J$  is normal lax monoidal and  $A \otimes \Delta_J(B) \cong \Delta_J(\sum_J A) \otimes \Delta_J(B) \to \Delta_J(\sum_J A \circ B)$  is an isomorphism. Moreover, the category of monoids is equivalent to the category of monoids relative to J.

PROOF. This proposition is a direct application of the dual of Lack and Street [2015, Theorem 1.2], as stated in Proposition 5.1. The characterisation of the category of monoids comes from [Altenkirch et al. 2015, Theorem 3.5].

PROPOSITION 1.31. The skew monoidal category  $[\mathbb{F}, \mathbf{Set}]$  induced by Proposition 1.30 (considering the canonical embedding  $\mathbb{F} \to \mathbf{Set}$ ) coincides with the one induced from the equivalence with  $[\mathbf{Set}, \mathbf{Set}]_f$  and is thus monoidal.

PROOF. This monoidal structure was introduced by [Fiore et al. 1999], but it can also be deduced from the uniqueness property derived from Proposition 1.30.

LEMMA 1.32. The monoidal structure on  $[\mathbb{F}, \mathbf{Set}]$  restricts to  $[\mathbb{F}, \mathbf{Set}]_{wb}$ .

Proof. It straightforward to check that the tensor product preserves well-behaved functors.  $\Box$ 

Proposition 1.33. The full and faithful embedding  $[\mathbb{F}^{\bullet}, Set] \to [\mathbb{F}, Set]$  given by right Kan extension

- has  $[\mathbb{F}, \mathbf{Set}]_{wh}$  as essential image, and
- restricts to a (skew) monoidal equivalence between  $[\mathbb{F}^{\bullet}, \mathbf{Set}]$  and  $[\mathbb{F}, \mathbf{Set}]_{wb}$ .

PROOF. For the first point, by full faithfulness, the embedding maps any  $F \colon \mathbb{F}^{\bullet} \to \mathbf{Set}$  to a functor  $\bar{F} \colon \mathbb{F} \to \mathbf{Set}$  which agrees with F up to isomorphism on all non-empty sets. Furthermore, by the standard formula for right Kan extension,  $\bar{F}(\emptyset) \cong \lim(F)$ . Now, the subcategory  $1 \xrightarrow{in_1} 2 \xleftarrow{in_2} 1$  of  $\mathbb{F}^{\bullet}$  induces a cofinal embedding, hence  $\lim(F)$  is in fact the pullback  $F(1) \times_{F(2)} F(1)$ . But the discussion following [Adámek et al. 2012, Theorem VII.1] (see also [Trnková 1969]) shows that this  $\bar{F}$  is well-behaved.

For the second point, note that the (bare) equivalence induced by the first item between  $[\mathbb{F}^{\bullet}, \mathbf{Set}]$  and  $[\mathbb{F}, \mathbf{Set}]_{wb}$  transfers the monoidal structure from the latter category to the former. To see that this structure coincides with the one of  $[\mathbb{F}^{\bullet}, \mathbf{Set}]$ , let us compute the tensor induced by the equivalence on any  $A, B \in [\mathbb{F}^{\bullet}, \mathbf{Set}]$ , letting  $\mathbb{F}^{\bullet} \stackrel{j}{\hookrightarrow} \mathbb{F} \stackrel{i}{\hookrightarrow} \mathbf{Set}$ :

$$\Delta_{j}(\prod_{j} A \otimes \prod_{j} B)(n) = \Delta_{j} \Delta_{i}(\sum_{i} \prod_{j} A \circ \sum_{i} \prod_{j} B)(n)$$

$$= (\sum_{i} \prod_{j} A \circ \Delta_{j} \Delta_{i} \sum_{i} \prod_{j} B)(n)$$

$$\cong (\sum_{i} \prod_{j} A \circ B)(n)$$

$$\cong \int_{p \in \mathbb{F}} [p, B(n)] \times \int_{q \in \mathbb{F}^{\bullet}} [\mathbb{F}(p, q), A(q)].$$

induced by Proposition 1.30, we can simply exploit its uniqueness property.

PROPOSITION 1.34. The skew monoidal categories  $[\mathbb{F}^{\bullet}, \mathbf{Set}]$  and  $[\mathbf{B}(\mathbb{N}), \mathbf{Set}]$  induced by the previous proposition, taking J to be the obvious full and faithful embeddings, are actually monoidal.

PROOF. For the case of  $[\mathbb{F}^{\bullet}, \mathbf{Set}]$ , we just showed that it is skew monoidally equivalent to  $[\mathbb{F}, \mathbf{Set}]_{wb}$ . But since the latter is truly monoidal, the first one also is.

For the case of  $[B(\mathbb{N}), Set]$ , this can be proved by adapting [Altenkirch et al. 2015, Theorem 4.2], weakening the condition for *type-theoretic universe* stating that El(one) = 1 by El(one) is not empty. Alternatively, one could exploit the skew monoidal equivalence with  $[\overline{\mathbb{F}}^{\bullet}, Set]$  proven later in Proposition 1.36 and the fact that this latter category can be proved monoidal by direct application of [Altenkirch et al. 2015, Theorem 4.2].

# 1.5 Step 2: the category S - DBAlg'

Given a signature S, it is straightforward to define an endofunctor  $\Sigma'_S$  on  $[\mathbf{B}(\mathbb{N}), \mathbf{Set}]$  with a relevant strength, so that  $\Sigma'_S$  - **Mon** are equivalent to  $\Sigma_S$  - **Mon**.

1.6 Steps 3 and 4: the monoidal equivalences  $[\mathbb{F}, \operatorname{Set}]_{wb} \simeq [\mathbb{F}^{\bullet}, \operatorname{Set}] \simeq [\operatorname{B}(\mathbb{N}), \operatorname{Set}]_{wb}$ 

The first equivalence  $[\mathbb{F}, \mathbf{Set}]_{wb} \simeq [\mathbb{F}^{\bullet}, \mathbf{Set}]$  was already exhibited in Proposition 1.33.

To prove the other equivalence, we use the intermediate category  $[\overline{\mathbb{F}}^{\bullet}, \mathbf{Set}]$ :

- (1) we first show that the restriction functor  $[\overline{\mathbb{F}}^{\bullet}, Set] \to [B(\mathbb{N}), Set]$  is a monoidal equivalence;
- (2) then we show that the full and faithful functor  $[\mathbb{F}^{\bullet}, \operatorname{Set}] \xrightarrow{\Sigma} [\overline{\mathbb{F}}^{\bullet}, \operatorname{Set}] \to [B(\mathbb{N}), \operatorname{Set}]$

- has  $[\mathbf{B}(\mathbb{N}), \mathbf{Set}]_{wb}$  as essential image;
- induces a monoidal equivalence between  $[\mathbb{F}^{\bullet}, \operatorname{Set}]$  and  $[\mathbf{B}(\mathbb{N}), \operatorname{Set}]_{wb}$ .

Proposition 1.35. The restriction functor  $[B(\mathbb{N}), Set] \to [\overline{\mathbb{F}}^{\bullet}, Set]$  is an equivalence.

PROOF. By [Borceux 1994, Proof of Theorem 6.5.11], it suffices to show that the functor  $\mathbf{B}(\mathbb{N}) \to \overline{\mathbb{F}}^{\bullet}$  as the Cauchy completion of  $\mathbf{B}(\mathbb{N})$ . It is easy to check that this is indeed the usual idempotent completion.

Proposition 1.36. The equivalence  $[B(\mathbb{N}), Set] \to [\overline{\mathbb{F}}^{\bullet}, Set]$  is monoidal.

PROOF. This can be proved either by application of the uniqueness property of Proposition 1.30, or more simply (because it doesn't require to unfold the definition of Kan extensions) by exploiting uniqueness property of Lack and Street [2015, Proposition 5.1], considering the restriction functor as the right adjoint (it can be shown in general that for any restriction functor that is an equivalence).

PROPOSITION 1.37. The full and faithful functor  $[\mathbb{F}^{\bullet}, \mathbf{Set}] \to [\overline{\mathbb{F}}^{\bullet}, \mathbf{Set}]$  defined by the left Kan extension

- has  $[\overline{\mathbb{F}}^{\bullet}, \mathbf{Set}]_{wb}$  as essential image, defined as the full subcategory of functors preserving the filtered colimit for  $\mathbb{N}$  over the canonical diagram  $j \downarrow \mathbb{N}$ , where j is the embedding of  $\mathbb{F}$  in  $\mathbb{F}^{\bullet}$ ;
- induces a monoidal equivalence between  $[\mathbb{F}^{\bullet}, \operatorname{Set}]$  and  $[\overline{\mathbb{F}}^{\bullet}, \operatorname{Set}]_{wb}$ .

PROOF. The proof is similar to that of Proposition 1.33. Indeed, the left Kan extension preserves the value of the given functor on any  $n \in \mathbb{N}$ , and the value on  $\mathbb{N}$  is exactly defined as the mentioned colimit.

Proposition 1.38. The image of the full subcategory  $[\overline{\mathbb{F}}^{\bullet}, \operatorname{Set}]_{wb}$  of  $[\overline{\mathbb{F}}^{\bullet}, \operatorname{Set}]$  through the equivalence of Proposition 1.35 is  $[\mathbf{B}(\mathbb{N}), \operatorname{Set}]_{wb}$ 

PROOF. The proof relies on the observation that a functor  $F \in [\mathbf{B}(\mathbb{N}), \mathbf{Set}]$  corresponds through this equivalence to a functor  $G \in [\overline{\mathbb{F}}^{\bullet}, \mathbf{Set}]$  mapping  $\mathbb{N}$  to  $F(\mathbb{N})$  and n to the subset of  $F(\mathbb{N})$  consisting of elements with support n (this can be obtained by unfolding the definition of the left or right Kan extension). Now, the fact that G preserves the canonical colimit  $j \downarrow \mathbb{N}$  means means that  $F(\mathbb{N}) = G(\mathbb{N})$  is the reunion of all the G(n), i.e. that F indeed only has finite support elements.  $\square$ 

# 1.7 Step 5: the endofunctor $\Psi_S$ on $[\mathbb{F}^{\bullet}, Set]$

Given a signature S, it can be easily shown that  $\Phi_S$ , as an endofunctor with strength on  $[\mathbb{F}, \mathbf{Set}]$  restricts to an endofunctor  $\Psi_S$  with strength on  $[\mathbb{F}^{\bullet}, \mathbf{Set}]$ . It can be shown to correspond to  $\Sigma_S$  and  $\Phi_S$  as endofunctors with strengths on  $[\mathbf{B}(\mathbb{N}), \mathbf{Set}]$  and  $[\mathbb{F}, \mathbf{Set}]_{wb}$  through the monoidal equivalences of the previous subsections.

We may proceed operation-wise. Let us treat the case of the arity for abstraction, the rest works all the same. Then,  $\Psi_S(F)(n) = F(n+1)$ .

First, let us consider the (adjoint) equivalence  $\mathbf{l} \dashv \mathbf{r} : [\mathbb{F}, \mathsf{Set}]_{wb} \to [\mathbb{F}^{\bullet}, \mathsf{Set}]$ , where  $\mathbf{l}$  is the restriction functor and  $\mathbf{r}$  the right Kan extension. Now, in the world of  $[\mathbb{F}, \mathsf{Set}]_{wb}$ ,  $\Psi_S$  becomes  $\mathbf{l} \circ \Psi_S \circ \mathbf{r}$ , and thus maps a functor F and a non-empty ordinal n to F(n+1), while and the value in 0 is the equaliser of  $\psi_S(F)(1) \rightrightarrows \psi_S(F)(2)$ , that is, of  $F(2) \rightrightarrows F(3)$ . Since F is well-behaved, this is isomorphic to F(1), as expected. Morphisms are also mapped as expected by  $\mathbf{l} \circ \Psi_S \circ \mathbf{r}$ , so that this functor is indeed isomorphic to  $\Phi_S$ .

Next, we consider the (adjoint) equivalence  $\mathbf{r}' \vdash \mathbf{l}' : [\mathbb{F}^{\bullet}, \mathbf{Set}] \to [\mathbf{B}(\mathbb{N}), \mathbf{Set}]_{wb}$ . In the world of  $[\mathbf{B}(\mathbb{N}), \mathbf{Set}]_{wb}$ ,  $\Psi_S$  becomes  $\mathbf{l}' \circ \Psi_S \circ \mathbf{r}'$ . Then,  $\Psi_S(\mathbf{r}'(F))(n) = \mathbf{r}'(F)(n+1)$  is the set of elements with

support n+1. Finally, applying  $\mathbf{l}'$  yields the set of elements with a non empty support, we obtain an isomorphic set:  $\mathbf{l}' \circ \Psi_S \circ \mathbf{r}'(F)(\mathbb{N}) \cong F(\mathbb{N})$ . More precisely,  $\mathbf{l}' \circ \Psi_S \circ \mathbf{r}'(F)(\mathbb{N})$  is (by definition of the left Kan extension) the set  $\{f[u] | n \in \mathbb{N}, f \in \mathbf{r}'(F)(n+1), u : n \to \mathbb{N}\}$ , quotiented by the relation  $f[u \circ v] \sim v' \cdot f[u]$  for any map  $v : n \to m$ ,  $f \in \mathbf{r}'(F)(n+1)$ , where  $v' : \mathbb{N} \to \mathbb{N}$  coincides with v for k < n, and is the identity otherwise. The above mentioned isomorphism maps such an element f[u] to  $u' \cdot f$ , where  $u' : \mathbb{N} \to \mathbb{N}$  preserves 0 and any k > n, and maps any  $0 < k \le n$  to u(k-1). Let us check the action of  $\mathbf{B}(\mathbb{N})$ : let m be a map  $\mathbb{N} \to \mathbb{N}$ . Then, m acts on  $\mathbf{l}' \circ \Psi_S \circ \mathbf{r}'(F)(\mathbb{N})$  by mapping an element  $f[u] \in \mathbf{l}' \circ \Psi_S \circ \mathbf{r}'(F)(\mathbb{N})$  to  $f[m \circ u]$ . Through the isomorphism between  $\mathbf{l}' \circ \Psi_S \circ \mathbf{r}'(F)(\mathbb{N})$  and  $F(\mathbb{N})$ , this induces a function  $F(\mathbb{N}) \to F(\mathbb{N})$  with mapping  $f \mapsto f[1, \dots, n] \mapsto f[m(1), \dots, m(n)] \mapsto (0, m(1), \dots m(n), n+1, \dots) \cdot f$ , for f with support n+1.

Checking the correspondence of the strength is similar.
